required to pay the dividend on the additional capital, which would show them that that capital had been profitably and judiciously expended. They might think that £69,558 was rather a small sum to carry into the balance sheet for depreciation, but he must remind them that that was the balance still available for depreciation, and took no account of the £108,000 which they had already written off that account. With regard to the obsolete plant, he told them last year that they had written off the whole of such plant at City Road. With regard to the obsolete plant, he told them last year that they had written off the whole of such plant at City Road. This year they had allocated to the demolition account the whole of the obsolete plant at Wandsworth, and after writing off the sum they had allocated for the present year, there was only £30,000 to the debit of the demolition account; and they had £69,000 left in the account. There were very few companies which were in such a really sound position as regarded their plant as they were. In regard to the business done, in spite of the check caused by the war during the last five months of the year, they had the pleasure of reporting another record in the new business. Last year and the previous year they created a record, and again this year they had a record with new applications of 5,206 km., which was easily ahead of anything they had secured in any previous year. That reflected the greatest credit upon their commercial staff. It had been obtained by the addition of 1,897 new consumers. bringing the total number of consumers to 24,212, the largest number that any London electric supply company could show. The increase in units sold was 2,269,418, or nearly 9 per cent.; the total sales for the year being just over 28 million units. With regard to the associated companies, the Bournemouth Co. had maintained its dividend at 7 per cent. and the Coatbridge and Airdrie Co. still continued to expand its business, the increase for the past year being the very substantial one of 1,841 km. The war had prevented the past year from being one of almost phenomenal prosperity with them. They had suffered very severely by the increasing stringency of the lighting restrictions which the Admiralty had imposed upon London and the surrounding districts; but in spite of those restrictions they had progressed to the extent had imposed upon London and the surrounding districts; but in spite of those restrictions they had progressed to the extent he had indicated. The war had also had a serious effect on in spite of those restrictions they had progressed to the extent he had indicated. The war had also had a serious effect on their staff; 120 members had responded to the country's call and were serving in H.M. Forces. He was sure the shareholders would approve of the arrangements they had made that those men should not suffer financially in any way. The fact that so many had responded to go to the front had necessarily thrown increased anxiety and strain upon those left behind. He would like to take that opportunity of testifying to the unswerving loyalty and cheerfulness with which those members of the staff who had stayed at home had worked the additional hours and submitted to the additional strain. They would expect him to say a few words about the Parliamentary position. When they met last year he had hopes that common-sense might prevail and that the Bill, of which they were the nominal proprietors, which was put forward by influential bankers, for the unification of the London electric supply, might have had a fair chance of becoming law. He was sorry to say that owing to jealousy nearly all the London companies opposed the Bill, and their, opposition reached such a height that the promoters felt it was no use wasting any more money, and they reluctantly withdrew it. It was not their fault that the position of electric supply in London was not now on a satisfactory basis. Their efforts, however, had not been altogether in vain, because this year three Bills had been introduced, one by the L.C.C., which was an exceedingly important Bill which followed almost exactly the same lines as their Bill of last year. The Council had adopted both of the suggestions which they made in their Bill last year. It provided for the acquisition of the companies by the L.C.C. or some statutory body to be created Bill last year. It provided for the acquisition of the companies by the L.C.O. or some statutory body to be created for the purpose, and the leasing back to them of their underfor the purpose, and the leasing back to them of their under-takings for a period of 50 years to be worked by them. It also defined exactly what price the companies should get at the end of the 50 years. They did their best to help the L.C.C. with their Bill, but apparently the incurable jealousies and the smallness of outlook of the London companies caused them to again oppose the Bill, with the result that the Council failed to secure the necessary three-fourths majority to bring it forward, and the Bill had therefore been with drawn. They had, however, put their hands to the three points which were of the utmost importance to shareholders drawn. They had, however, put their hands to the three points which were of the utmost importance to shareholders in the London electric light companies—first that it was a fit and honourable thing that they should have their period of purchase extended to 50 years; second that the best results were to be obtained not by municipal ownership and management but by municipal control and company management; and, third, that it was fair to place the settlement on such a basis that, instead of being dependent upon the result of some arbitration, those who were engaged in the supply of electrical energy to London should know exactly what they were going to get at the end of 50 years' time, so that they might be able to make proper provision for the redemption of their capital. He thought it was a very great gain to have had those principles embodied in a Bill put forward by the LCC. Ten of the companies put forward a Bill of their own, and it might come as a surprise to the shareholders when he and it might come as a surprise to the shareholders when he told them that although those companies threw out the Bill which the County of London Co. promoted last year on the ground that it was foolish to ask the L.C.C. for 50 years, the associated companies had adopted that proposal in their Bill. The companies, apparently, could not agree among themselves, and their Bill had been withdrawn too. As far as the

directors of the County of London Co. were concerned, they did not intend to allow the question to rest where it was. They had a very clear view as to what was the proper policy to pursue, and they proposed to forward the unification of the electric supply of London by every means in their power. He had already alluded to a possibility of their coming into closer working relations with the South London Co. They had acquired a very large area in the Romford district and they proposed to go forward with the lighting there, and by next year he hoped to be able to tell them that they had commenced a supply there; and step by step they proposed as opportunity offered to follow up their policy of doing their utmost to unify the supply, and place the electric supply of London, as far as they had power to do it, on a satisfactory and sound commercial basis. The outlook for the current year was the most difficult matter that confronted him. We were in the middle of a great war, and none of them knew when it was going to end. At the present time conditions were somewhat unfavourable for electric supply companies owing to the dislocation in coal prices and other difficulties. They would do the best they possibly could to meet those conditions. Both the gas companies in London had increased their prices, and, although they would do it reluctantly, in might be necessary for them to ask some of their customers conditions. Both the gas companies in London had increased their prices, and, although they would do it reluctantly, it might be necessary for them to ask some of their customers to share with them the burden of the excessive cost of coal while the war lasted. If they found it necessary they would do that in order to protect the interests of the shareholders, and he had no doubt that the consumers would regard any increase in the price of current as part of the sacrifice which they would have to bear in order to carry on the war. He was glad to say that up to date the applications for new business were slightly in excess of those up to the corresponding period last year, and the units sold had increased by 4 per cent. cent.

Mr. F. W. REYNOLDS seconded the motion.
Mr. J. J. BISGOOD congratulated the board upon the report and also in regard to their policy for unifying the supply of electricity to London. No matter what happened in the future, it would always stand to the credit of the board of that company that they suggested a solution of that great problem.

The report was adopted.

### Metropolitan Electric Supply Co., Ltd.

MR. W. HARRISON CRIPPS presided on Tuesday, at Winchester House, E.C., over the annual meeting of this company. After reviewing the finances as given in the report, he said that in regard to the capital expenditure, the money was raised partly by a further issue of their 3½ per cent. debentures and partly against the reserve fund. It was spent partly upon generating and distributing plant and partly in providing connections for new consumers. At Willesden, in addition to minor improvements, they had installed a new 4.000-kw. Parsons turbine. They had had nine months' experience of this machine and found that it was saying them a large amount in coal , over the annual meeting of this company. and found that it was saving them a large amount in coal, water and oil, thus materially reducing their running costs. It was working in the most satisfactory way. They had also bought some freehold land in the Holborn district and had erected a building to accommodate large storage batteries, the effect of which would be to save the generation of many kilomatts at Willardon on the peak load. During the last faw effect of which would be to save the generation of many kilowatts at Willesden on the peak load. During the last few years they had been making considerable additions to their reserve fund: thus during the three years 1908 to 1910 they placed £15.000 annually to reserve. In 1911 this was increased to £17.000, in 1912 to £20.000, and in 1913 to £22,000. This year they proposed making a similar addition to the fund. He would remind them that when they had Marylebone, and their generating station at Sardinia Street, considerable sums had been put aside against the depreciation of those properties for which they received under the two arbitrations properties for which they received under the two arbitrations payment in full using the money they obtained in buying new plant for the remaining parts of their undertaking. These reserves thus became available to increase the amounts set aside in respect of the remaining plant, much of which had been acquired within the last twelve years. If the past year had been a normal one the position of the company, judging from the results of the first six months, would have been oute satisfactory, but the year was not a normal one. When they made up their accounts in July for the first six months they made up their accounts in July for the first six months there was a satisfactory increase both in new business and receipts, the result showing a satisfactory margin over costs. The actual number of new customers in the year was 1,620. The increased connections had been 1,550 kW., or an equivalent of 50,000 25-c.p. lamps. This was practically as good a progress as they had made in any one year. The new connections were at present coming in at a favourable rate. In spite of the war they were in excess of the corresponding nections were at present coming in at a favourable rate. In spite of the war they were in excess of the corresponding period of the previous year. In August, like a bolt from the blue, the war was upon them, upsetting every calculation. They seen had difficulty in keeping up their coal reserves and the prices began to rise. They had to part suddenly with some of their most experienced workmen; they had also to make provision for guarding their works and the extent their coal reserves and the prices began to rise. tions of their mains, and it at once became evident that their expenditure during the last half of the year would be increased. October arrived a new unforeseen loss of revenue had faced. They must bear in mind that, owing to the to be faced.

situation of their undertakings, chiefly in the West of London, the main source of income was from the sale of light, and October, November and December were the most important and profitable months for selling light; indeed, as much light was consumed during these three months as was the case in the six summer months of the year. Just as this important period commenced the order came for reducing all light to a minimum. They did not complain of this. They supposed it was necessary, but the shareholders had had to sacrifice a considerable part of their income for the general safety of London. To show the effect of this, he might mention that the revenue for lighting in their London areas decreased by over £10,000 in the last quarter of the year. The reason why the net decrease was no greater than about £2,000 was due to the large amount of new business they had been able to secure in the western areas. He only gave this as an explanation for the fall in revenue, which was in no way due to any permanent diminution of their business. It was one of the incidents of the great war. How long it would last who could tell, but sooner or later it would pass, and he hoped November and December were the most importone of the incidents of the great war. How long it would last who could tell, but sooner or later it would pass, and he hoped that the trade and prosperity of the country, upon which the electric supply industry depended, would have a quick and vigorous revival. During the past year an attempt had again been made to consolidate the electric supply of London. The Bill which the London County Council was to introduce failed owing to it not obtaining the necessary two-thirds majority of the whole Council. Most of the companies, subject to the settlement of certain details, were not necessarily in opposition to the Council scheme, the essential of which was the purchase by agreement by a new authority of the present companies of London. The new authority was to delegate its powers, safeguarded in many respects, to a new company to companies of London. The new authority was to delegate its powers, safeguarded in many respects, to a new company to take over the actual working of the undertaking. The companies, failing any satisfactory agreement with the London County Council, had a Bill of their own to effect a combination of the majority of the present undertakings. This Bill was to provide for the alteration of the present terms of life and to place the future purchase of the undertakings on a more satisfactory footing. These two Bills, with certain modifications, were not inconsistent with each other, but their Bill had had to be withdrawn in deference to the views expressed by the Chairman of Ways and Means that no private business of such magnitude should be undertaken during the present session. They believed that a proper combination of the present companies would reduce costs and would ultimately be an advantage to the consumers of electricity. They did not regard the matter as dropped, but merely postponed did not regard the matter as dropped, but merely postponed to a more favourable season. The year had been an anxious one to their staff, and had entailed much extra work. The directors wished to thank them all for what they had done, and would especially mention their two chief officers. Mr. Highfield, the engineer and manager, and Mr. Cunliffe Owen, the secretary for the zeal and devotion which they with and would especially mention their two chief officers. Mr. Highfield, the engineer and manager, and Mr. Cunliffe Owen, the secretary, for the zeal and devotion which they, with other members of the staff, had shown in the interests of the company during this very trying period. No less than 58 of their employés responded to the first call and were now away at the front. If these men served their country with the same faithfulness that many of them for years past had served the company the British Army would contain no finer body of men, and they knew that when they returned it would be with honour to themselves and their country. He wished to speak well of those who still remained in their service. Many of these also would have liked to have joined, but the board felt that they were equally doing their duty by their work in keeping up a regular supply of electricity, one of the most essential necessaries for London at the present time. They could not let their men leave them for the war without doing something towards the support of their families during their absence. The directors had made some provision for this.

Sir J. Pender, Bart., seconded the motion.

Mr. H. L. Cripps expressed his approval of the Chairman's statement that it was intended to proceed with the Bill for amalcamation when the time was opportune. He felt great confidence that amongst all the business men of the London County Council, no matter what their politics might be, there was a very strong feeling in favour of the policy which the Chairman had indicated, and which had been expressed in their own Bill.

The report was adopted.

their own Bill.

The report was adopted.

#### Braunton Electric Light and Power Co., Ltd.

At the annual meeting recently held it was reported that the At the annual meeting recently held it was reported that the net revenue account showed a balance of £238. The directors recommended a dividend of 5 per cent (less income tax) on the cum, pref. shares, amounting to £23, a dividend of 2½ per cent, on the ordinary shares (less tax) £63, writing off a further £30 from formation expenses, and 5 per cent, for depreciation of machinery, plant and accumulators, and 2 per cent, off mains, cables and services, amounting to £100, leaving £22 to be carried forward. The net revenue account showed that £234 was yielded from private lighting supplies, £77 from contract lighting, and £50 from contract pumping.

Mr. YEO, who presided, gave figures showing the advance made annually since the company was inaugurated a few years ago, and considered the position of the undertaking most satisfactory.

satisfactory,

### Electrical and Industrial Investment Co., Ltd.

An extraordinary general meeting was held on Monday at Electrical Federation Offices, Kingsway, under the presidency of Mr. E. Garcks, when the Chairman formally proposed the following resolution for reducing the capital of the company :-

following resolution for reducing the capital of the company:—

That the capital of the company be reduced from £400,000 divided into \$900,000 six per cent. cumulative preference shares of £1 each, 100,000 on which have been issued and are fully paid, 100,000 issued and fully paid seven per cent. preferred ordinary shares of £1 each, and 100,000 deferred ordinary shares of £1 each, and 100,000 deferred ordinary shares of £1 each, and refully paid, to £314,500, divided into 200,000 six per cent. cumulative preference shares of £1 each, of which 100,000 have been issued and are fully paid, 110,000 seven per cent. preferred ordinary shares of £1 each, of which 100,000 have been issued and are fully paid, and 90,000 deferred ordinary shares of 1s. each, all of which have been issued and are fully paid, and are fully paid, and that such reduction be effected by cancelling capital which is lost, or is unrepresented by available assets to the extent of 19s. per share upon each of the 90,000 fully paid deferred ordinary shares of £1 each, which have been issued and are now outstanding, by reducing the nominal amount of each of such shares to 1s., and by converting the 10,000 unissued deferred ordinary shares of £1 each into 10,000 unissued preferred ordinary shares of £1 each.

Mr. GAROKE remarked that he fully explained the reasons

Mr. GARCKE remarked that he fully explained the reasons for the resolution at the recent annual meeting, and he might say that while they had not received a single proxy against the proposal they had received a large number in favour of it.

Mr. CUNNINGHAM seconded the resolution, and it was carried.

Subsequently a similar resolution was passed by the holders of the deferred ordinary shares of the company.

### South London Electric Supply Corporation, Ltd.

South London Electric Supply Corporation, Ltd. The gross receipts for the year 1914 were £55,030, while the expenditure was £25,431, leaving £29,599, plus £728 brought forward. After placing to depreciation account £5,416 (making the fund £50,000) and writing off special items capital account £978, also making provision for the dividend on 6 per cent. cum. pref. shares due October 1st last, and accrued to the end of the year 1914, debenture and other interest accrued, etc. £14,428, there remains £15,899. Out of this the board recommend a dividend on the ordinary shares at the rate of 5 per cent. for the year, amounting to £13,000, carrying forward £2,899. During the year new connections representing the equivalent of 38,742 (35 watt) lamps, or 1,355 kw., were added to the company's system, making a total connection at the end of the year of 340,866 (35 watt) lamps, the equivalent of 11,900 kw. The units sold during the year amount to 6,153,241, and show an increase of 412,015 or 7.2 per cent. over the previous year. The ratio of total costs to revenue is 46.2 per cent. The plant, machinery and mains have been maintained out of revenue in an efficient condition. The report refers to the position of the two London Electric Supply Bills which are not to be proceeded with at present. at present.

... ... Total ... Expended in distribution Total connections ...

Annual meeting, March 23rd.

#### Salisbury Electric Light and Supply Co., Ltd.

The report for 1914 states that the generating plant has been sufficient to meet the output and the whole of the plant is in thorough working order and capable of dealing with a considerably increased demand. The profit on the year's working, including £1,098 brought forward, amounts to £6,994, and after paying £1,044 interest on debentures and an interim dividend at the rate of 4 per cent. for the half-year, amounting to £700, there remains £5,250. The directors recommend that a further dividend at the rate of 8 per cent. for the half-year be paid, making with the interim dividend, 6 per cent year be paid, making with the interim dividend, 6 per cent for the year, and that £2,400 be carried to reserve, leaving £1,450 to be carried forward.

Mr. F. E. GRIPPER presided at the annual meeting, held on March 9th. He first referred to the death of the Chairman, Mr. W. M. Hammick, who was practically the founder of the company. They were hoping to induce Mr. Woodrow, a Salisbury man, to become chairman. The company had had quite a good year. In spite of war troubles and the great difficulty there had been in the matter of coal transit, it had been the most successful year they had had. The staff had responded extremely well to the call of their country in joining the colours. At the commencement of the war they had 23 members of the staff, and 30 per cent. of those were now serving with the colours. The company had made arrangements to give those men a generous allowance during the ments to give those men a generous allowance during the time they were away, and were reserving their positions as far as it was possible to do so. There had been a considerable amount of economy in lighting since the war began, and that had reduced the amount of current which would have been used under ordinary circumstances. In spite of that, their receipts on the revenue account were £138 larger than last year, while the costs of running were only £88 more, about half of that amount being due to the increased cost of coal. Altogether they had £352 more to deal with than they had last year. They thought it advisable, under present conditions, to carry forward a substantial amount, so that they might have provision for any trouble that might turn up. But for the existing conditions he thought the directors would have been justified in paying another 1 per cent., but the more prudent course was not to increase the dividend this year and to live in hopes of being able to do so next year. The company was in a very sound financial position.

Mr. A. C. BOTHAMS seconded, and the report was adopted. The CHAIRMAN mentioned that the directors had elected Mr. J. C. Wigham, one of the representatives of Messrs, Edmundson, to fill the vacancy on the board caused by the death of Mr. Hammick.

### Brompton and Kensington Electricity Supply Co., Ltd.

The revenue account for 1914 shows a credit balance of £30,271, plus £7,153 brought forward, and £322 balance of interest received and accrued, making a total of £37,746. After deducting £1,273 for interim dividend on the 7 per cent. cum. pref. shares, and £7,360 interim dividend (free of income tax) at the rate of 9 per cent. per annum for the half-year to June 30th on the ordinary shares, the directors recommend that £29,114 be dealt with as follows:—Written off cost of investments £1,100, written off the shares in and advances to the Brompton and Kensington Accessories Co., Ltd., £4,000, reserve fund account (raising it to £46,000) £6,500, dividend on the preference shares for December half-year £1,052, dividend on the ordinary shares for December half-year at the rate of 11 per cent. per annum, making 10 per cent. for the year, £9,315, income tax on interim dividend £521, directors' additional remuneration £1,000, leaving to be carried forward £5,626. £5,626.

Year.	8-0.P. lamps con- necsed,	Inc. in s-c.p. lamps.	Cus- tomers con- nected.	Gross receipts.	Expendi- ture	Not receipts.	Av. price per unit.	Div. on ord. shares.

The annual meeting was held yesterday.

### Edison Accumulators, Ltd.

MB. BERNARD M. DRAKE, M.I.E.E., presided on Friday, at 2, Duke Street, S.W., over the first annual meeting.

The CHAIRMAN, in moving the adoption of the report, said the results shown in the balance sheet were fairly satisfactory, due allowance being made for the abnormal times through which they were passing. The item under the profit and loss account for staff, offices, and selling expenses might appear high, but they would understand that in initiating the industry of the company, which was new to this country, it was necessary to be constantly running cars for demonstration purposes, and enquiries had to be followed up closely so as to ducate the public as to the results which might be expected poses, and enquiries had to be followed up closely so as to educate the public as to the results which might be expected under various working conditions, and the particular ones for which their products were best suited. It had also been necessary to prepare special designs to suit the conditions prevailing in England, which in many cases were different to those in America and elsewhere. They would notice amongst the assets an item of £4,845 under the heading of "royalties paid in advance." He might explain that in order to obtain the concession for the sole rights of the Edison battery for England a sum of about £5,000 had to be paid in advance. This amount, however, was being credited to the company on orders as placed with the Edison Co. of America. For part of the period under review they were unfortunately paying for two sets of offices; their former offices, however, had now been let, so that this extra outlay would not recur. At the end of the year there were sufficient unexecuted orders on the books two sets of offices; their former offices, however, had now been let, so that this extra outlay would not recur. At the end of the year there were sufficient unexecuted orders on the books to have enabled them to show a profit had it been possible to obtain the necessary equipment in time. As regarded the future, they would be pleased to hear that encouraging reports were being received concerning the results obtained with the vehicles now at work. Not only was the cost per ton-mile comparing very favourably with that of other road transport systems, but the reliability, ease of manipulation, and quiet running of the Edison accumulator vehicles were proved to be advantages with which no other system could hope to comrunning of the Edison accumulator vehicles were proved to be advantages with which no other system could hope to compete. An objection sometimes raised to the use of electric vehicles was the trouble of recharging and the time occupied in this operation. This, however, would largely disappear with increasing use and additional charging stations. One special feature of the Edison battery was the rapidity with which it could be recharged. Another important point with regard to the working of electrically propelled vehicles was that the cost of generating and supplying current was steadily decreasing, whereas the cost of petrol or other fuel for the internal-combustion engined commercial and private cars had been continuously rising. To give them a practical example, he might mention that one Borough Council engineer had found that four 2-ton tipping wagons had replaced no less than 11 horses and carts, besides doing the work of refuse collection more efficiently. Although the first cost was heavier, it was claimed for the Edison battery that being composed of more durable materials it could successfully withstand vibramore durable materials it could successfully withstand vibrations and hard work which would shorten the life of lead batteries, so that in the end the cost for traction work would be lower. The life of a lead battery was now pretty accurately known, and was short, but the life of the Edison battery, judging from examinations of batteries which had been in use and showed no deterioration whatever, would be indefinitely long. The Edison battery had also a very distinct advantage in that it suffered no deterioration from being completely discharged, or even left in a discharged condition, a state of affairs which was very prejudicial to lead batteries. Mr. Edison was reported to have said that in his opinion the nickel iron was reported to have said that in his opinion the nickel iron alkali battery would play an important part in the transportation of the future. This statement was already verified in America, but in England they were slow to move in anything new, and it was often difficult to overcome the want of enterprise shown by the older established stores, cartage contractors, and other firms, who were content to wait until their more up-to-date competitors had shown what could be done. Arrangements had been concluded with the firm of Drake and Gorham, Ltd., of which he was chairman, under which their widely-spread organisation would be available for pushing the sale of Edison vehicles, especially in Lancashire and Cheshire, for which district they had purchased a two-ton truck which was constantly employed in making demonstrations. He was glad to say that the orders received since the expiration of the period covered by the balance sheet had been most satisfactory, in fact they amounted to over three-fifths of the total during the period covered by their balance sheet. He had every hope, therefore, that when next they met the directors might be in a position to recommend the payment of a good dividend.

Col. H. C. L. Holden seconded the motion.

A shareholder remarked that the statement was most encouraging, and he hoped the board would be in no hurry to pay dividends.

The Chairman said that was advice they rarely received from

shareholders

The report was adopted.

#### Oxford Electric Co., Ltd.

SIR HENRY MANCE presided at the annual meeting, held at Oxford on March 5th. The Secretary (Mr. H. Eeles) read the Chairman's financial memorandum, which showed that the capital expenditure was less by £4,623 than for 1913. In the revenue account the expenses were adversely affected by increased price of commodities, increased taxes, and heavier The item of street lighting showed a decrease, as the account had been charged with the cost of providing a system of incandescent lighting to take the place of the large arc lamps which were extinguished some weeks ago. Cost of carbons had largely increased owing to shortage of imports. The balance of gross profit was love by about \$250. had largely increased owing to shortage of imports. The balance of gross profit was less by about \$2500, approximately 1 per cent. on the ordinary share capital. The Chief Engineer (Mr. F. H. Francis) read a report on the engineering work of the year, plant alterations, mains extensions, new installations, etc. There seemed to be a growing demand for 2 and 3-H.r. motors for such work as boot-repairing, firewood making, etc. In regard to new services, 1913 was an exceptionally good year, and but for the war they would probably have broken the record in 1914. The price of coal had increased nearly 4 per cent., and fuel oil for the Diesel engine by 31 per cent. They were deprived of the use of the Diesel engine for a considerable period in consequence of an accident in September. It was now in use again, but with a reduced output. The It was now in use again, but with a reduced output. The repair of the third evinder, the one severely damaged by the accident, was now under consideration, and would be taken in hand as soon as possible. Their present stock of coal would last eleven weeks, and with the assistance of the Diesel engine three months. The prospects for lower prices of fuel were not encouraging not encouraging.

Sir Henry Mance, in the course of his address, said that he had taken the view that in this period of great national stress, when investors would be disappointed in many of their sources of income, it was their duty to pay to the shareholders every shilling they could which had been fairly earned and which they could prudently do. They would continue to act on that policy. They were doing remarkably well when the war broke out and looked like having a revenue £1,000 in excess of the previous your but they were effected by the state of the latest and the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the previous year, but they were affected by the colleges and allied institutions needing less current, and by the prohibition of private outside lighting. Personally, he believed that the citizens of Oxford were in greater danger during a thunder-storm than they would be from the visit of a hostile aeroplane. Some of the staff had volunteered to do the duty of one of Some of the staff had volunteered to do the duty of one of the employes who was at the front, by means of overtime, for which they asked no extra remuneration. The issue of preference shares made last month had been several times oversubscribed for. The shares were offered to the shareholders a few days before the Treasury minute appeared. He saw one of the Secretaries to the Treasury and was informed that there was no objection to the issue, but it would be necessary to communicate with the Treasury when they applied for a Stock Exchange quotation. Sir Henry said that he did not suppose that the most sanguine amongst them anticipated that the war would be over before the autumn, and that being so they must not expect any increased demand for current on the part of the colleges and allied institutions. Still, if they were to put the question to him, "were they downhearted?" he would reply emphatically "No!"

The report was adopted.

#### Waste Heat and Gas Electrical Generating Stations, Ltd.

THE annual meeting was held in Newcastle-on-Tyne on the 10th instant. Mr. E. L. Pease, who presided, said that Dr. Simpson (the Chairman) and Mr. F. S. Newall were prevented by illness from being there that day. The capital vented by illness from being there that day. The capital expenditure on buildings, generating plant and machinery totalled £273,994, which was nearly £3,000 less than last year. The reduction was due to one of their customers having exercised his option to purchase some electric motors and other plant which that company had supplied on hire-purchase terms. The value of the plant sold under the agreement was £3,922, but on the other hand they had paid on capital account during the year £980. The profits for the year were £39,001, 23,522, but on the other hand they had paid on capital account during the year £980. The profits for the year were £39,001, an increase of £756 over the previous year, and they were transferring an extra £1,000 to the reserve fund. The profits available for distribution were £40,611, as compared with £37,710. Since the outbreak of war there had been a slight decrease in the amount of waste heat obtained at some of the stations; compared with the corresponding period of the previous year, it represented in units of electricity about 7 per cent reduction. This did not mean, of course, that the company's profits during that period had necessarily decreased in the form of fixed charges which were paid by the electric power companies for the use of the stations. He would not venture to give any forecast as to the probable results of this year. The company's supplies of waste heat and gas depended largely upon the regular working of coke ovens and blast-furnaces, and if those businesses were seriously affected by the war they would themselves be affected also. The company had not erected any new generating stations since the last report, but the directors had had recently under consideration the advisability of installing some additional plant at Weardale power station, in view of a more efficient utilisation of the gas received from the coke ovens, and they had also made the gas received from the coke ovens, and they had also made arrangements to erect some further plant at the company's Grangetown power station with the object of maintaining greater output from the plant installed there. If those works were carried out it was estimated that they would involve an expenditure of £35,000 to £40,000, which would be within the

company's available cash resources.

The report was adopted.

It was decided to distribute £1,000 amongst various relief funds.

### Chelsea Electricity Supply Co., Ltd.

Chelsea Electricity Supply Co., Ltd.

In the absence of Mr. Davies, who is on service with the Red Cross in France, Major W. F. Woods presided on March 11th, at Winchester House, E.C., over the annual meeting. He said that during the part of the year previous to the declaration of war, the number of units generated and sold showed a very satisfactory increase, and revenue was growing steadily, but in the latter part of the year the restrictions imposed on street lighting had caused a considerable shrinkage in the sale of current, attributable to the reduction of the lighting of shops and other outside illumination, the earlier closing of licensed premises, the cessation of most forms of entertainment, and the general practice of economy in businesses and households. In the first half of the year there was an increase of 40,932 in the units sold, or an increase of about 2 per cent., as compared with the first half of 1913, but by the end of the year this was converted into a decrease of 108,983 units, or about 2½ per cent., as compared with the previous year. Added to this, the increased price of coal, which was from 25 to 30 per cent higher than before the commencement of the war, coupled with the difficulty of obtaining regular supplies owing to the dislocation of traffic on the railway systems, caused the directors to prepare them for a possible falling off in the net profits in 1915. Unfortunately, the immediate outlook, so far as coal prices were concerned, were not encouraging, but the Government were now taking steps to give electricity supply undertakings assistance in deliveries, and they hoped to reduce the expenditure by using more oil fuel in connection with the Diesel plant. Notwithstanding the adverse circumstances, the receipts and expenditure were practically the same as in 1913, the expenditure by using more oil fuel in connection with the Diesel plant. Notwithstanding the adverse circumstances, the receipts and expenditure were practically the same as in 1913, and the net amount available for distribution after payment of interim dividends and debenture interest was £29,058. There was considerable delay in getting their Diesel plant to work. It was still in the hands of the contractors, and certain questions with them were still outstanding. The engines had, however, been at work during the latter part of 1914, and they believed that their anticipations in regard to their effect in reducing the fuel costs would be fully justified. They proposed to utilise this portion of the plant to a considerable extent during the current year. The amount paid to the Central Co. for current purchased had been £1,077, as against £641 in 1913. The increase in 30-watt connections during the year was 7.854, and but for the untimely circumstances of the war this item would doubtless have been considerably increased. In regard to the London power Bills, now withdrawn, whatever might happen in this connection in the

future, the directors might be relied upon to see that the interests of the Chelsea Co. were properly safeguarded, and the shareholders would, of course, be asked for their approval of any scheme by the companies dealing with this very difficult question. The directors had interested themselves in the question of recruiting men for the Army and personally interviewed all members of the staff who had not previously enlisted and who were eligible for service, to ascertain (withinterviewed all members of the staff who had not previously enlisted, and who were eligible for service, to ascertain (without, however, bringing any pressure to bear) whether there were good reasons for their abstention. He was glad to report that 34 men out of 122 had joined the colours, or more than 25 per cent. of the staff. The directors had made provision for their dependents with a promise of reinstatement on return. The thanks of the shareholders were due to all those members of both the indoor and outdoor staff who, during a very difficult time, had loyally carried on the work of the company. He also expressed their gratitude to the police, and especially to the special constables, who had given their ungrudging services during the dark hours of the night, and often during the most inclement and unpleasant weather, for the protecthe most inclement and unpleasant weather, for the protection of the company's stations.

Mr. H. E. Beeton seconded the motion, and the report was

adopted without discussion.

Mr. S. Beeton was re-elected a director, and a vote of thanks was passed to the special constables for their services in guarding the company's properties.

#### Derby Lamp Works, Ltd.

At the statutory meeting, held at Moorgate Place on March 12th, it was stated, according to a report which has been supplied to us by the secretaries, that the number of preference shares applied for fully reached expectations and practically 50 per cent. of the ordinary shares offered as 3s. 6d. raid had been applied for, and shareholders of Metalite, Ltd., were congratulated on having exercised their rights to such a substantial extent. They had purchased a few new machines, principally labour-saving devices, which the works manager thought desirable. They were selling some of the machinery which, owing to their not making filaments, was row unnecessary. They had invested £250 in the Sheraton Glass Manufacturing Co. in order that they might secure a constant supply of bulbs at minimum cost. They went to allotment on January 15th with a clear working capital of £7,000. This was a satisfactory result considering the financial difficulties consequent upon the war. Finance once satisfactorily arranged, said the Chairman, the present state of affairs undoubtedly militated in their favour; they could not have started business at a more favourable time—a time At the statutory meeting, held at Moorgate Place on March affairs undoubtedly militated in their favour; they could not have started business at a more favourable time—a time when their enemy competitors were entirely shut out of the market. After the war, Austrian and German manufacturers who in the past had found this country such a convenient dumping ground, would find that the energy and initiative of the British lamp makers had "changed all that." The speaker went on to refer to the management, which he confidently believed was going to make "our company not only successful, but one of the foremost lamp factories in this country." The works manager, Mr. J. L. Green, "has had an experience of which many in this trade may well be envious." "Although we only went to allotment two months ago we already have a satisfactory production, and what is envious." "Although we only went to allotment two months ago we already have a satisfactory production, and what is at this stage perhaps the most important point, we are satisfied that the lamps we are producing are second to none in quality." This "rapid progress" however would hardly have been possible if the directors had not financed the company out of their own pockets for over two months before allotment. Those who were shareholders in Metalite, Ltd., were under a considerable obligation to them in that respect.

We are informed that in reply to questions which were asked, the directors stated that they were satisfied that the working capital available was sufficient to bring the company to a paying basis, and that they had been offered a contract for the whole output, also one for 20,000 lamps per week. These contracts were under consideration.

### STOCKS AND SHARES.

The recovery in markets to which we alluded last week is continuing steadily. Although in Consols there is still no chance of realising stock, for most of the other gilt-edged securities a demand is distinctly noticeable. This investment enquiry has the virtue of spreading, and, for the first time in many months, we are in the position of being able to record that buyers are searching the electric lighting list for what they consider to be cheap shares. The Home Railway group is decidedly better.

What is known as the Miscellaneous market, wherein are comprised most groups of industrial securities, is the most active in the Stock Exchange; and of all its varied sections, that for oil is pre-eminently strong. One of the main features of the week turned out to be a further sharp advance in the price of Marconis, though the movement lacked sufficient staying power to hold the quotation at the best level reached.

The especial point that makes the electric lighting market The recovery in markets to which we alluded last week is

noteworthy is the fact that a number of the shares which hitherto have been practically unsaleable at their quoted levels can now be realised without difficulty. The change would be remarkable were it not remembered that, under the restrictions imposed by the Government, Stock Exchange jobbers are not allowed to sell shares unless they have actually got them. One direct consequence of this is that, whereas in the ordinary way they would sell, taking a business risk of replacing the shares at an early opportunity, they cannot do so unless armed either with the shares themselves or with the positive knowledge that they (the jobbers) can get them. And as, in market circumstances so unique as those at present ruling, the timid buyer is frightened when he finds his chance of acquiring cheap stock looks like becoming practicable, so also the hitherto anxious seller no sconer gets a bid for his shares than he promptly raises his price, in the hope

of getting more.

If in this exposition of circumstances there savours aught approaching the iteration regarded by good authorities as so damnable, the writer on Stock Exchange topics must fain cover his defence with the statement that the aforesaid set of conditions comes into play so frequently, and yet so un-expectedly, that he is compelled to fall back upon it in en-deavouring to set the market picture clearly before those

interested in its view.

Within the next two or three weeks all the electricity supply shares will be quoted ex-dividend, and it will be possible to reinstate that table of yields on money invested which previously, since war broke out, might have given a false impression instead of a correct one. The quotations below are mostly cum dividend, allowing for which, the leading ordinary shares can be bought to pay 5½ to 6½ per cent, on the money. The trouble, as hinted above, is to secure shares; and in cases where only a month ago there were blocks up to 500 on offer, to-day's investor will learn from his broker that, if he is fortunate, he may be able to secure 100 at some comparatively high price. In addition to the following prices, we may add that bargains were done to-day (Tuesday) in South Metropolitans at 9s. 9d., and in Bournemouth Ordinary at 10½.

We append our usual list of representative stocks and shares Within the next two or three weeks all the electricity supply

at 9s. 9d., and in Bournemouth Ordinary at 20s.
We append our usual list of representative stocks and shares

in the electric lighting markets:-

One of the features in the Home Railway market is a point se in Metropolitan Consolidated stock. The chairman at One of the features in the nome rise in Metropolitan Consolidated stock. The chairman at the recent meeting was mildly bullish, and he went quite frankly into the question of the Government's obligation with making up the traffic receipts. What the Government's obligation with frankly into the question of the Government's obligation with regard to making up the traffic receipts. What the Government guaranteed was a certain income from certain sources, reduced through the carriage of troop trains. The Government had not guaranteed their net income out of which the dividend was paid, and it therefore followed that they had not guaranteed the dividend itself. The price of the stock has risen to 30. Surplus Lands are higher at 56. Districts are 10s. better at 17½. Underground Electric income bonds have progressed still further towards recovery of the full amount of the recent £3 deducted for the dividend. Central Londons are steady. There is even a little business in East London ordinary stock, on the basis of 3½. It may be recalled, incidentally, that the price of East Londons at the time war broke out was 5½.

Brazilian Tractions have been fluctuating within compara-

Brazilian Tractions have been fluctuating within compara Brazilian Tractions have been fluctuating within comparatively narrow limits round about 53. The exchange from Rio rose to 13\forall d. at the end of last week, and later came back to the neighbourhood of 13d. The company continues to declare its quarterly dividends of 1\forall per cent.—that is, at the rate of 6 per cent. per annum; and although there are qualms as to its retention, which make the price somewhat wobbly every three months as the declaration date draws near, the speculative investor is manfully buying shares which, so long as the existing payments continue. give him the handsome return existing payments continue, give him the handsome return

existing payments continue, give him the handsome return of 11½ per cent. on his money.

Marconis touched 33s., a fresh advance of 2s. 3d., but the effort met with large sales of pre-moratorium shares, and this took the price back again to 36s. 3d. Holders who had been running Marconis just before war broke out were allowed, under the Government's scheme, to keep them in suspense at 38s. 9d. so long as that price was not reached, but on shares becoming saleable at 1 15/16, the bulls could be called upon either to pay for the stock or else sell it. So many selling limits were fixed at the price mentioned that the recent buyers became exhausted before the sellers did. Market theory contends that while the Marconi Company is under Government control, the Treasury will recoup whatever loss the undertaking may be put to by reason of naval and military exigencies.

taking may be put to by reason of naval and military exigencies.

The Consolidated Gas & Electric Co. of Baltimore, very familiar to investors over here, is about to issue Two-year 5 per cent. Notes at 98, with conversion privileges into common stock at 115. Out of this issue arises the rather important question whether the British investor will be allowed to participate, supposing the Treasury decline to allow the stock to be offered here at all. Some weeks ago, official prohibition was applied to a bond-offer by a first-class American Railroad but if the Baltimore Co. chooses to allot its Notes by way of rights, the patriot may well be puzzled in his search for some method whereby the British investor is to be debarred from subscription. subscription.

method whereby the British investor is to be departed from subscription.

Mexico Tramways bonds have gone back 10 points in each class, for reasons too hopelessly well known to call for comment. Other than these, the changes are not large enough to quote. As a curiosity may be mentioned the record of transactions in Kalgoorlie Electric Lighting ordinary shares at threepence; the preference mark 4s. 6d.

The Telegraph market is generally steady, with the Eastern group in the ascendant. Eastern ordinary put on 1½, the preference a point, and Globe preference ½. Westerns were a better market at 13½. Great Northerns gained £1. We have already pointed out that investment demand has penetrated this section, and that the difficulty is not to sell shares, but to buy them at anything like the quoted prices.

The Manufacturing list is firm, holding its rises of the past week or two. Electric Constructions advanced a little, and Henleys at 14½ are the fraction un. British Westinghouse preference rose to 39s. 6d., at which price sellers came in and reduced it to its former level of 38s. 9d. Armament shares are decidedly weaker. Lord Kitchener's speech on Monday night foreshadowed a Government scheme for enabling em-

ployés of large contracting firms to share in whatever of extra benefit such firms derive from the war. As it had already been assumed in the market that the armament companies were scarcely likely to raise their dividends next month, this announcement by the Minister of War did not stimulate prices. The rubber market, on the other hand, is good, with a number of the best-class shares in such demand as to lead doily to better prices. daily to better prices.

Interesting points have arisen in connection with certain of the Government telephone contracts in respect of private lines between the Stock Exchanges of London and the provinces. The Government took over the lines altogether when vinces. The Government took over the lines altogether when war broke out, and for about six months the brokers had to rely on trunk calls. Now the Post Office offers to cancel the remainder of whatever contracts may be outstanding, or, alternatively, to continue them at a reduction of 33 per cent. in view of the shrinkage of Stock Exchange business caused by the Treasury regulations. Readers tired of acrostics might take this as a week-end problem, asking themselves how they would act in like circumstances if they were brokers.

#### MARKET QUOTATIONS.

#### SEARCHLIGHT PROJECTORS.

By C. W. DENNY, A.M.I.E.E.

(Concluded from page 349.)

The use of flame or mineralised arcs necessitates a different form of mirror and different controlling mechanism. The fisme arc projectors, and also the use of petrol-oxygen in projectors, the writer hopes to deal with at a future date. In consequence of the excessive heat generated by the electric arc, it has been necessary to give special attention to the ventilation of the projector body and mirror. When projector lamps are consuming current up to 200 amperes, it will be readily appreciated that some means must be provided to carry away this heat. It may be mentioned that a metallic mirror, after being a considerable time in use, reached a temperature in the neighbourhood of 700° F., with an arc taking approximately 180 amperes. heating up of projector bodies and fittings, more especially in the case of small projectors, and even large projectors when used in a sheltered position, is a source of trouble in handling, and is always dangerous in the case of crystal glass mirrors.

A suggested method of cooling the barrel was recently brought before the writer's notice. It consisted of ribbing the barrel with light angle sheet Items. In thick, and also the back of the mirror frame. In the case of the latter special flat plates were allowed to press lightly against the mirror (metallic mirrors being used) as a means of rapidly conducting the heat to the ribbed cover, which materially lessened the temperature rise of mirror and barrel. Of course, the ribs on the barrel were omitted where doors, ventilators, and other mountings interfered with their use. It was claimed

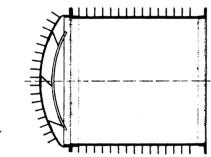

Fig. 3.—Section of Projector with Cooling Ribs.

that the radiating surface of the projector body was increased 75 per cent. by the ribs. A rough sketch of such a method is shown in fig. 3, the usual ventilating hole being omitted in the sketch. A further advantage is the use of wooden handles, or, to be more correct, iron handles with a wooden covering or sleeve, on mirror frames and front glass doors, as the usual iron handles become too hot to be comfortable after prolonged use.

Mechanical Movements of Projectors.—The balancing of the projector body on its trunnions is usually accomplished by having one of the trunnion guide rods screwed and passing it through a screwed hole in the trunnion bracket at each side of the barrel.

Any movement of the barrel parallel to its axis can be made by revolving the screwed trunnion rods. It is preferable that the screwed rods should be coupled together by chain gear or other approved means whereby both rods revolve at the same time, keeping the barrel quite parallel with the guide rods. This is of the first importance on military projectors, where adjustments of the barrel have to be made rapidly and often in action. The movements of the projector barrel through 30° above and below the horizontal and the describing of a complete circle by the turntable are accomplished by means of worm gearing, which is so arranged that it can be thrown out of action should it be desirable to move the projector rapidly by hand.

Various friction plates and clamping screws are in vogue for stiffening the movements of the barrel and base when operating the projector by hand. Difficulties sometimes occur with devices of this kind, inasmuch as the operator often throws out the worm gearing for obtaining the slow motion before sufficiently tightening up the clamping plates, the result being that the projector body, if not perfectly balanced, swings rapidly through the range of its lower movement, and in the case of a large projector comes with a heavy bump against the fixed stops which limit such

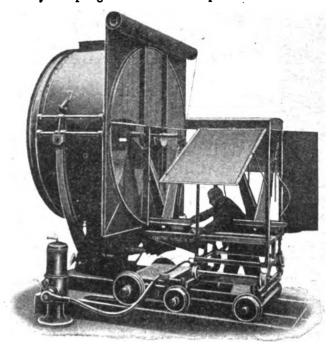

FIG. 4.—PROJECTOR FOR COAST DEFENCE SERVICE.

movement. Such rough usage is not conducive to the long life of the mirror (if of crystal glass) or other delicate parts of the optical apparatus.

Various suggestions have been put forward with regard to a "one-wheel control" arrangement for projectors, that is, operating the movements of the barrel and turntable at one and the same time by one wheel. By means of suitable clutches, either turntable or barrel can be operated

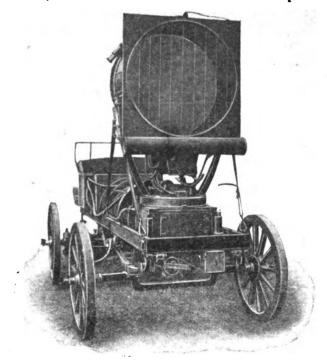

FIG. 5.—FIELD SERVICE PROJECTOR.

separately, the advantages in support of this arrangement being the ease of manipulation with one hand-wheel, as against two, and that the operator always has one hand free to attend to the lamp, &c. Although there are these points in favour of such a device, the writer does not advocate its use, owing to the somewhat complicated clutch mechanisms employed.

Numerous improvements have recently been made in connection with switches and resistances; for projectors the latter should always be of the adjustable type and well

ventilated, combined switches and resistances arranged in the projector base being amongst the more recent improvements. Improvements in arc deflecting magnets, arc-centring gear, &c., are more or less of recent date.

Soveral very efficient types of portable generating sets are now on the market for use with field service projectors, or on ships where electrical equipment is not general. These usually consist of a gasoline engine and multipolar dynamo mounted on a light cast-iron bed-plate.

Some approximate particulars of a double-cylinder four-cycle engine and dynamo are:—Output, 30 to 35 amp. at 110 volts; weight, 650 lb.; length, 42 in.; width,

20 in.; height, 30 in.; R.P.M., 750.

Fig. 4 shows a projector arranged for coast defence. It is controlled electrically from a distance, in such a way that the operator is remote from the beam of light, and also in the best position for observation. Projectors of this class are preferably provided with lamp carriages, to enable the substitution of a new lamp for one whose carbons are consumed to be carried out with the minimum of delay, so as not to interrupt the light longer than neces ary.

A characteristic type of Continental field service projector is shown in fig. 5, mounted on its carriage. It is supplied with current from a generating set on another equally mobile carriage. The use of the metallic reflectors has permitted the construction of light and easily manipulated carriages for projectors up to 36 in. in diameter, which are extremely useful in hilly or mountainous countries.

# THE EFFECT OF THE PRESENT COAL POSITION ON THE BUSINESS OF ELECTRICITY SUPPLY.

[COMMUNICATED.]

WITHIN the last three years the public have had at least three demonstrations of the fact that the price of coal will be raised on the slightest pretext, and that within a few days of the first advance in prices coal merchants who have entered into quite large contracts to supply regularly week in and week out a stipulated amount of coal of a certain quality, will unblushingly declare that they are unable to obtain the stipulated amount, and that to their intense sorrow they needs must curtail supplies.

This state of things lasts for a short time, when the harassed station engineer almost implores the coal merchant to procure for him coal of any burnable quality at what he is pleased to term, vaguely, anything like a reasonable price,

as his stock is showing signs of depletion.

Within a day or two the kindly merchant informs the station man that although he (the merchant) cannot supply the demand himself, yet after considerable trouble he has persuaded the firm of So-and-so to let him have about a two or three weeks' supply at a figure about 60 per cent. or 70 per cent. higher than the engineer has been paying.

Naturally the engineer resents being bitten, but as his place was not originally laid out for coal storage on a large scale, he soon has to come down and accept the coal merchant's prices, which in the few days of haggling have again

advanced.

Now this sort of thing is going on all over the country at the present time; therefore, it is hitting each and every district in a most vital part, viz., its electricity supply, at a time when it is of the utmost importance that things should

go rapidly and smoothly along their proper path.

There may be in one or two places a genuine shortage of coal or wagons to convey that coal, but to nothing like the extent which the coal merchants pretend. This is proved by the fact that after the engineer has agreed to pay the extortionate prices asked for fuel, he continues to get just sufficient to keep him going at the enhanced prices. Make no mistake, the writer speaks from bitter and costly experience; your coal merchant knows to a nicety what is your storage capacity, and adjusts his tales of scarcity, high prices and impossibility of delivery to suit the exact con-

ditions under which he knows the plant has to work as regards coal.

It is true that he has entered into a business contract to supply so much coal at a certain price, but it is also equally true that he will not supply that amount of coal at that price as long as he can obtain higher prices from other people. In short, he will declare that he cannot get your coal, and therefore must be relieved from his contract. He will also, within an hour of telling this tale, sell the coal he has solemnly agreed to deliver to you, to someone else at a much higher price.

Now, such callous and disgraceful breaking of contracts should not be permitted. The prosecution of such offenders in one or two industrial centres should be taken up by a combination of coal consumers formed for the purpose. This may, perhaps, be a difficult matter, hampered as the supply stations are by being under municipal control in

many instances.

In one way, the antics of the coal merchant, resulting in the uncertainty of coal delivery as soon as a slight strike, or rumour of a strike, crops up, should send more power users on to the mains of electricity supply works, and it should be possible in such cases to pick up a good many small and medium power loads at prices between 4d. and

1 d. per unit.

This, however, will only shift the burden from the shoulders of the works owner or manager on to those of the supply station engineer. What is necessary is some means of controlling the supply of coal without the intervention of the middle-man, who has shown time and again that he can only be trusted to break his agreements whenever it pays him to do so. This, of course, implies the control of one or more collieries, which at once introduces difficulty.

The municipal ownership of the majority of supply stations stands in the way of concerted and powerful action, as the Local Government Board would not sanction any share in such a venture; again, the case has to be considered from several aspects. Not all the coal raised would be steamraising coal of the type required, and to market the remainder would necessitate a capable selling organisation, as the ordinary coal merchant would not purchase or sell

coal from these collieries on any consideration.

Added to the above difficulty is the one of delivery. Stations on the railway with a siding could make arrangements to supply so many wagons to the railway company, and enter into an agreement with them that these wagons were to be dispatched regularly at certain convenient times as long as it was possible to work the railway. This contract should be in its essence as binding as a Government contract, and it would be worth the while of any power station which had been harassed and bled to pay a little extra to the railway company for the privilege of obtaining such a contract.

Consumers not on the railway would have to provide their own wagons, and might do much good by using electrically-driven coal wagons for this purpose. The batteries could be charged up overnight, and the continued use of the wagons would result in other persons in the town watching the result and obtaining such wagons themselves, and so offering a load desirable in every way to the power station. The original difficulty, however, of obtaining control of the colliery is the greatest difficulty, and to the writer it does not seem possible to surmount this at present.

Many of the largest industrial firms possess their own collieries, and antics such as those at present indulged in by the coal merchants were the cause originally of these concerns entering into the colliery business.

The matter, however, is important for every supply station, whether it has or has not sufficient storage capacity to render itself immune from this evil for some months.

Storage of coal means extra handling, once into and once out of storage at the least; it occupies valuable space, and means that unless the coal is regularly removed from storage and burnt the calorific value will be greatly depreciated, and in turn this demands a regular putting into and taking out of storage of a considerable quantity of coal. There is also the risk of spontaneous combustion to be considered, and the fact faced that its prevention costs money, in that space must be allowed for thorough breaking-up of the coal into fairly small bulk.

The solution of putting the power stations at the pit mouth is very easy to propose, but two important considerations are overlooked. One is that such policy means the scrapping of a good deal of modern and exceedingly valuable plant of large size, and the other is that it means fairly long transmission of the power so generated. The latter problem is not at present a commercial success in these islands, judging from the results attained by the various power companies who have been in the business for several years. Perhaps the easiest and most direct way out of the position would be for the leading men in the power supply industry to meet and take steps either to force one of our existing organisations to move the Government in the matter, or, failing that, to form an association to influence Members of Parliament to take up the passage of a measure putting the supply of coal to power stations on the same basis as the supply of war material; that is, the supply must be maintained at the prices agreed upon and in the quantities promised, even if to do so required the enlistment of colliers in a special manner and at special rates of pay, with the stipulation that refusal to work would be treated as mutiny in the Army or Navy would be treated.

The work of the power stations is vital to the well-being of the nation. The coal merchant has repeatedly shown his indifference to all considerations other than those of profit, and should be treated as an unpatriotic and untrust-worthy person.

# RUSSIAN TRADE AND ELECTRICAL PROSPECTS.

(COMMUNICATED.)

VITAL as the present war is to all the Allies, Russia is undoubtedly the country which will profit most by the conflict, for it will complete the work begun by the institution of the Duma and the guarantees for constitutional government; and will make good the loss of prestige and credit sustained by Russia in the Russo-Japanese war. It is effecting consolidation of the people, confirming the stability of the constitutional régime, and bringing Russia into close and amicable relations with her Allies. In short, the "awakening" of Russia is being completed by this war, and once peace is declared, rapid industrial development will occur. Hitherto the country has been chiefly agricultural, but the natural wealth is beyond estimation, and there is room for the development of practically every industry. The dredging of rivers and building of railways and factories which have already begun will proceed faster than ever, and with them will now arise an enormous demand for machinery and manufactured products of every kind. Internal resources will be inadequate for some time to come, to keep pace with this rapid development.

There is an immense potential power field in Russia, both in production and utilisation, and in the present state of engineering it goes without saying that a very large percentage of this power will be supplied electrically. The business boom of two or three years back was accompanied by great extension in the use of electricity in Russia. It is now used extensively in textile mills, in oil fields, in electrochemistry and in blast furnaces. Further, the advantages and possibilities of electrical development are fully appreciated by the Russian Government and many municipalities, so that in this vast country, which has recently advanced centuries in decades, and is now prepared to take up to the full extent 20th century industrial existence, without being burdened by any of the impedimenta of gradual evolution, there is an unparallelled field for electrical development. Though some of the equipment required for new and extended central stations, hydro-electric plant and transmission, tramways, railways, telegraphs, factories, streets and homes

will be supplied by existing and new Russian firms, there will necessarily be enormous imports of manufactured electrical material of all kinds for years to come, and British firms can accelerate or retard Russian development, gain trade for themselves, lose it to rivals, or compel premature manufacture on the spot, according to the nature and degree of their activity.

Hitherto Germany has enjoyed the major portion of all Russia's foreign trade, actually controlling a large fraction of the exports as well as supplying the greater part of her imports, but the advantages Germany has had in respect of geographical position and excellent commercial organisation will be entirely outweighed in future by her shattered credit, crippled resources, and possibly disintegrated national structure, not to mention the formidable barrier of sentiment which she has thrown up against herself by her ill deeds and which will take years to demolish.

On the other hand there was already, before the war, a strong movement in Russia in favour of English goods (which the amiable German did his best to gratify by selling German-made goods with forged English trade marks). Many English firms had realised and begun to take advantage of the possibilities of Russian trade, and now there should be no hesitation in so doing, for English firms have been more than semi-officially invited to enter the Russian field, and all Russian sentiment will henceforth be more strongly than ever in our favour. We have, however, in the German, a trader thoroughly versed in every phase of organisation and enterprise -honourable and dishonourable. His ability will not be affected by the war and, though his opportunities will be much less favourable, we must remember that the degree of his necessity will be the measure of his efforts, and we have tremendous leeway to make up both in methods and results

The total value of Russian imports of all kinds was three times as great from Germany as from England in 1910, and by 1914 the ratio was 4: 1, the respective values being nearly £40,000,000 from Germany and a bare £10,000,000 from England. Our electrical exports to Russia compare even less favourably with those from Germany. In 1912 Germany exported to Russia £230,000 worth of dynamos, motors and transformers, i.e., twice the value of her corresponding exports to England, and about the same value as her corresponding exports (each) to Italy and Argentine. Of this total, machines and transformers up to 220 lb. weight were worth £52,000; from 220 to 1,100 lb. £66,000; and over 1,100 lb. £112,000. The total exports of electrical machinery of all kinds from England to Russia were valued at only £59,900 in 1913. German exports of glow lamps to Russia were valued at £466,000 in 1912, i.e., 50 per cent. more than the value of lamps exported to England, and 25 per cent. of the total exports of this class from Germany. We sent £200 worth of metal filament lamps to Russia in 1913. It is interesting to note that we send about £250,000 worth of belting to Russia (about 15 per cent. more than Germany does), and our wide connection in this class of goods should prove helpful in introducing British electrical equipment to Russian power-users-assuming a certain amount of cooperation among British firms. Immediately before the war Russian electrical imports must have been worth close on £2,000,000 per annum—possibly more —and soon after the war their value is likely to become greater still. There is an immense market positively waiting to be taken-much of it we can take if we get busy now and go the right way about But Germany's defeat in the field does not mean that she will give up the Russian (or any other) market without a severe struggle.

Many of the ramifications of German influence and control in the Russian electrical industry have only been realised since the outbreak of war severed some of the hidden arteries which used to feed apparently

independent concerns. The great German electrical firms operating in Russia were under direct German control, and had a very complete series of working agreements and "understandings," which permitted them all to do good business yet never allowed any dissension or competition giving outside firms a reasonable chance of success—simply another example of the vast possibilities of co-operation with "competitors." Just as since the war large quantities of electrical goods have arrived in Russia from "neutral" countries, branded artlessly with neutral trade marks which do not suffice to disguise the Germanic origin of the whole; just as since the war German "commercials" travelling with neutral passports (purchased or worse) have sold these neutral goods; so in the years preceding the war many independent firms, "Russian," "Belgian," and others, were German at the core. The institution of really independent concerns was at once crushed by ruthless use of the whole capital and influence of the German combinations and the banks and diplomats supporting them.

Besides availing itself to the full of every legitimate method, German commercialism, like German militarism, has been characterised by highly organtreachery and deceit—underhand machinations being often employed when honest endeavour might have attained the same end with the single objection (in German eyes) that the extent of German dominance would have been prematurely disclosed. It is an established fact that representatives of German firms have given gratuitous and "disinterested" assistance to those responsible for municipal and other electrical schemes in Russia, to such purpose that the ultimate scheme and specification have appeared in such form that German products alone could fill the bill. This and other even more dubious methods do not appeal to the British mind, but with contract after contract, aggregating hundreds of thousands of pounds per annum secured by such means, we must at least add fresh weapons to our commercial armoury.

While it is unnecessary to credit Germany with any particular commercial morality, it would be equally foolish to underrate her commercial ability, and some of her methods should undoubtedly be employed by us. There is no reason, for instance, why our banks should not be as powerful agents in industrial development and association of interest here as in Germany. The commercial activity of German embassies, and the application of "diplomatic pressure" to secure trade for Germany, find no counterpart in our State. Our consular service and the Board of Trade are all right so far as they go—so far as they can go—but fully qualified commercial and technical attachés reporting to a Department of Commerce can alone render the service desirable.

Remote control is quite inadequate in seeking to trade with Russian markets. Without frequent visits by an experienced representative or, better, permanent travelling representatives, it is impossible to gain the necessary intimate knowledge of conditions and developments. For years past Belgian and German firms have been represented in Russia by commercial engineers speaking French, German and Russian, and dealing directly with small as well as large clients. To the energy and intimate knowledge of Russian and Polish trade conditions possessed by their representatives. German firms owe most of their success in this field. The favourable geographical position of Germany is a factor of much less importance than is generally supposed.

There are some British-owned factories in Russia and a number of agents (actual or potential) well versed in the language and trade conditions, and if a British firm do not wish at present to send out a man of their own, they may still be represented effectively on the spot. Indeed, it is advisable in any case to examine closely what co-operation is

possible with firms and agents already well-established in the country.

The language difficulty has prevented many British firms from venturing in Russian markets, but the latter are so valuable that the difficulty must be faced and overcome. Circulars and correspondence in English will result in very little business, any thus obtainable being generally already fixed in destination. French and German are chiefly used by Russians for scientific and other publications, for which a wide circle of foreign readers is desired, but Russian is the only language which will permit exporters to get into really close relations with clients and take full advantage of the enormous business to be done with smaller concerns, any one of which, under existing circumstances, is likely to develop much and rapidly in importance, and will naturally continue most of its earlier connections. In the past only too many British firms have employed German "foreign correspondents" in their offices. Surely it is now sufficiently clear why a docile, hard worker and skilled linguist could be obtained at the wage of a junior clerk. It is not flight of imagination or prejudice. but a sober fact, that a high percentage of German clerks in this country used to send home each week business reports which in the aggregate cost their employers far more than they saved in wages.

There is a good demand in Russia for standard electrical equipment of English design and manufacture but, particularly among the smaller traders where price is everything, it is essential to be able to offer apparatus at least as good as the corresponding German lines and at competitive prices.

In the phrase "German goods are adapted to local requirements" (vide consular reports without number), lies the reason for order after order going to those who are not our friends. If we are learning better than our take-it-or-leave-it attitude, our improvement is terribly slow. It is totally inexplicable why so many British manufacturers will see no further than the end of their noses, and quite fail to realise that what they lose on perhaps nine out of ten special orders, they recoup handsomely on a steady stream of orders following the tenth special job. The whole matter reduces simply to this, that there are firms who will go out of their way to satisfy special requirements, who do this at reasonable prices and yet make an annual profit. Those firms, whatever their nationality, are the ones to whom the future belongs.

It times of peace it was well worth executing special (as distinct from freak) orders, and in the critical years following the declaration of peace it will be yet more worth while, when the tremendous demand for war munitions collapses as suddenly as it arose and the world's trade is redistributing itself as it certainly will do. Have not manufacturing firms in this country repeatedly gone to Germany for special work in the past because they could not get the attention they desired at home, and will they never apply this lesson to their own morals?

There is undoubtedly a tendency on the part of the average British manufacturer to ignore or attach insufficient importance to the broader principles and customs of trading in foreign markets. In respecting these, the German excels, and by sheer method and attention to minutiae he succeeds, though it is an unprejudiced fact that he has never been popular abroad.

(To be concluded.)

Science and Industry.—The Institute of Industry and Science has, by permission of the Lord Mayor, called a "Conference of Leaders of Industry and Science" at the Mansion House, for Thursday, March 25th, at 3 30 p.m. There will be a discussion on "The Co-operation of Science and Industry."

#### ELECTRIC COOKING.

#### By W. R. COOPER, M.I.E.E.

(Abstract of paper read before the Institution of Electrical Engineers, March 11th, 1915.)

So far, in the cooking field, electricity has been chiefly in competition with gas, in smaller houses and flats; in larger houses coal ranges are more usual, because the cooking is more continuous and because hot water is required in large quantities. Naturally the revenue from an electric cooker replacing such a coal range is considerably greater and more profitable than that from a cooker in the smaller class of house, because the large cooking consumer, unlike the large lighting consumer, has an appreciably better load factor than the smaller consumer.

In the example to which the author wishes to refer, the number of persons normally in the bousehold is from eight to nine, and there is a good deal of cooking, though not of an elaborate kind. A fairly large cooker, by Messrs. Purcell & Nobbs, was therefore selected, of which the following are brief particulars :-

				Maximum loading			
Oven { upper, 2,000 wat lower, 1,000 ,,	ts }	•••	•••	total,	3,000	watte.	
Grill		•••	•••		1,500	••	
Two 8 in, hot plates	•••		•••	each	1,500	"	
One 6-in. hot plate	•••	•••	•••	•••	750	,,	
The electric heating of de	maati		- :	at a n		Hon the	

is financially impracticable. It is a question of tariffs. Pending the taking-up of this matter seriously by central-station engineers, it was thought best to install a separately-fired coke boiler for supplying the hot water.

The average consumption was found to be about 2 KW.-hours per person per day in the winter-time and about 16 in the

summer. The consumption per week was approximately 110 kw.-hours in the winter-time and, say, 90 kw.-hours in the summer.

Before electric cooking was adopted the average annual cost (based on the two preceding years) with coal was as follows:—

Electrical	ener	gy ior	ngnt	and	orner	pur-		_	_
poses	•••	•••	•••	•••	•••	•••	₽9	0	0
Meters	•••	•••	•••	• • •	•••	•••	1	0	0
Coal	•••	•••	•••	•••	•••	•••	13	10	0
									_
							<b>£2</b> 3	10	0
ith electric	oook	ing the	result	for t	he yea	r was			•
ith electrical	energ	y for li	ght, &	C., 89	above	•••	as fo	llov	<b>7</b> B
Electrical Electrical	energ energ	y for li y for c	ght, & ooking	c., as (incl	above uding	 fixed	as fo	llov	<b>7</b> B
Electrical	energ energ	y for li y for c	ght, & ooking	c., as (incl	above uding	 fixed	as fo	llov	<b>7</b> B
Electrical Electrical	energ energ 5,02	y for li y for co	ght, & ooking hours	c., as (incl (ave	above uding	 fixed	as fo	llov 16	<b>7</b> B
Electrical Electrical charge) 1'04J. po	energ energ 5,02 er KW	y for li y for co	ght, & ooking hours	c., as (incl (ave	above uding rage I	fixed price,	as fo	llov 16	3

In the above no credit has been allowed for certain advantages of the electrical system. The number of KW.-hours for lighting and other uses has been taken to be the same in both cases, and a correction has been introduced for a short period of defective meter working. The net result is seen to be an increase in cost of £8 18, 91. per annum over the cost of cooking with coal. The initial outlay was as follows:

Electric cooker	• • •	•••	•••	£23	15	6
Cooking utensils	•••	• • •	•••	2	5	0
Wiring for supply to cooker	• • •	•••		9	4	5
Boiler and connecting up say	•••	•••	10	6	4	
-,						
				245	11	3

Later, a porringer taking 800 watts and having three heats was added, which, with wiring, cost £4. This was found to be a great convenience. The above are list prices.

There are many cookers on the market of lower price than the

heavy proportion of the whole, and must inevitably remain high so long as engineers adhere to the fashion of using screwed tubing. Wood casing might be employed equally well. The author sees Wood casing might be employed equally well. The author sees no reason why armoured cable should not be used without further

A main double-pole switch should be fixed in a handy position

near the cooker, and a pilot light should be fixed so that the cook cannot help seeing whether the power is on or off.

It is most important to have the branch switches in a position where they are not only easily seen, so that the various heats are ascertainable at a glance, but also easily operated. For this reason is every undesirable to mount them on the side of the cooker; switches are heat placed on the wall behind the cooker somewhat to one are best placed on the wall behind the cooker, somewhat to one side. The author prefers a s nall fuse on each circuit to one large one for the whole cooker

A thermometer should be provided. The usual rough-and-ready method of judging the temperature of an oven is to open the door and thrust in the hand. The oven here considered requires 10 minutes for the temperature, as shown by the thermometer, to rise from cold to 350° F.

It has been freely stated that the loss in weight with coal or gas cooking is, say, 30 per cent, whereas it is, say, 15 per cent. with electric cooking. Actually, it is impossible to give a fixed figure. If there is much fat the loss will be heavy, whereas, if the joint is lean, the loss will be much less.

Figures which the author obtained in the course of ordinary working, and which show the loss of weight, may be of interest :

LOSS WHEN COOKING BY COAL

Character of jo	of joint. Original weight.		Loss.	Remarks.	
1. Rolled ribs o 2. , , , , , , , , , , , , , , , , , , ,		lb. oz. 4 7 4 2 3 13 4 9	29½ % 29 % 18½ % 23 %	Rather leau.	
Average	•••	•••	25 %		

LOSS WHEN COOKING BY ELECTRICITY

Character of joint.	baracter of joint. O iginal weight.		Remarks.		
1. Rolled ribs of beef 2. " " 3. " " 4. " " 5. " " 6. " " 7. ", "	1b. cz. 3 14 3 8 3 13 4 1 4 1 4 12 4 6	13 % 141 % 18 % 20 % 121 % 141 %	Joint lean and rather underdone Joint rather fat Joint rather fat		
Average	•••	141 %			

Extravagant claims in this, as in any other direction, are to be deprecated. It is forgotten that the roasting of joints is but a small part of the total cooking.

The author found that a suitable routine, in the case of joints, is first to raise the temperature to 350° F.; the joint is then put in, the temperature is allowed to fall to 250° F. by switching off, and is kept (by switching on the low heat occasionally) between 250° F. and 300° F.

The energy required to heat an oven is not as great as might be expected. In the present case the oven, with an input of 3 kw., reaches a temperature of  $250^{\circ}$  F. in 5 minutes, i.e., by the expenditure of 0.25 kw.-hour. For small operations, such as keeping dishes hot, the author has found it convenient to use a hood of tin-plate, preferably double, as shown in fig. 1, which can be placed over any hot plate as a heating element. It is provided with a low metal stand and deflecting plate so that the heat is not excessive near the hot-plate; or an asbestos sheet may be used to give

It is desirable that an oven should heat up so ravid'y that the heat losses have not much time to take effect, after which the input can be reduced simply to supply these losses. For these asons the time taken to reach a temperature of 306° F. should not exceed 10 minutes.

Accessory apparatus is often desired, and then a plug circuit is accessory apparatus is often desired, and then a plug circuit is inevitable; plugs are sometimes provided with shields, which give some protection. The author thinks, however, that it would be more satisfactory to fit a metal ring round the socket (as in fig. 2) so that the pins are not exposed so long as they are alive. This ring should preferably be earthed. The live metal of the socket for the reception of the pins of the plug is often brough the reception of the pins of the plug is often brough the present to the surface than is necessary and can be ton-had be nearer to the surface than is necessary, and can be touched by persons when cleaning.

persons when cleaning.

In portable utensils the pins are often exposed when the socket is in position, if it is not pushed home. These pins should be housed, as indicated in fig. 3.

One of the troubles with flexible wire is the annoying way in which ordinary qualities break on account of being continually subjected to bending. The layman cannot put the matter right without calling in assistance—which means delay and a bad advertisement for electrical methods. Many of the usual twisted

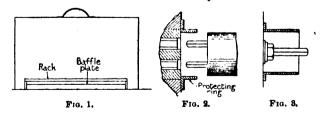

FIG. 1.—"PORTABLE" OVEN. FIG. 2.—PROTECTION OF SOCKETS. Fig. 3.—Protection of Pins by Housing.

fixible cords are unsuitable for this class of work, and special

types should be used. These are now becoming available.

The author has recently subjected a number of samples to a bending test. It is apparent from these tests that ordinary flexible wires vary very much in their mechanical properties, and that it is not necessary to depart from the ordinary type to get excellent results.

It is generally recognised that electric cookers should be earthed so as to ensure immunity from shock. There is no question that the earthing should be to a water pipe, and that the effectiveness of the earthing should be tested. Earthing clips and wires should be more substantial than is generally the case. It would be an advantage if such clips carried a red metal label bearing the words "Earth Connection—Must not be Removed."

The mixing of earthed and unearthed apparatus is much more dangerous than to discard earthing altogether. The plain form of wall-plug should not be permitted in the kitchen : there the thre pin variety with earthed connection should be used, and leads should be in flexible metal tubing, the utensil, tubing, and plug being properly connected together. Similarly, tumbler switches with metal covers should not be permitted on cooking apparatus except with an earthed connection.

The Council of the Institution should draw up rules as to earthing. At the same time the standardisation of socket connections on electric irons and similar apparatus might be considered. Manufacturers should realise that there is nothing to be gained by every manufacturer having his own size and spacing of pins. To the user it is exasperating to have to buy a particular socket connection for a particular piece of a parameter.

O scasionally the consumer is fortunate enough to have the offer of a very low flat rate. More generally, however, the tariff involves a primary charge which may depend on the rateable value of the house or upon the amount of lighting and plant installed, and, further, a secondary charge of so much per KW.-hour consumed. As a possible consumer the author chiefts to raying a consumed. As a possible consumer the author objects to paying a consumed. As a possible consumer the author objects to paying a heavy primary charge when he may be using only a cooker. In comparing the cost of electric cooking with coal cooking, this heavy charge may be sufficient to deter him from making the experiment with a system of which, as a householder, he has no first-hand experience. That is the attitude that must be borne in wind. mind.

That the primary charge provides for the fixed charges of generation for the lighting load is a fair basis on which to go. In that case it should bear some relation to the maximum lighting load. During the last few years many station engineers have complained that the lighting load was much reduced through the use of metal-filament lamps; yet there seems to be no tendency for the percentage charged on the rateable value to be reduced.

If the assessment basis is found to be generally expedient, then the author would suggest that the rateable value should be treated as an elastic quantity, which to the discretion of the engineer. It

as an elastic quantity, subject to the discretion of the engineer. It is obviously absurd that a consumer should be made to pay a larger primary charge than is necessary simply because he has a garden. The engineer should remember that a high assessment probably carries a higher load factor with it, and he should, therefore, try to meet the consumer, as far as possible, on the primary charges.

The second point that has impressed the author is the great importance of a low secondary charge, such as 0.5d. This is important, because cooks are often wasteful, and the housholder soon finds that it is less serious to waste a halfpenny than a penny. Moreover, such waste is all to the good for the station; it means a er load factor, and for that reason merits a lower price after a certain quantity of electrical energy per kw. has been consumed. In the case here discussed, some of the tariffs in use by certain members of the Point Five Association would have shown very little difference in the total cost between electricity and coal. This fact is surely an achievement.

In the case of the cooker, to which reference is here made, over a In the case of the cooker, to which reference is here made, over a period of 13 months, the oven showed no defect, and the grill only gave one partial failure. The hot-plate is the most vulnerable part of an equipment. Maintenance is a subject of vital importance to the consumer. If, say, a hot-plate, or an oven, goes wrong, he does not like to be kept a week or more for the repair to be made. Moreover, he would like to know quite definitely how much the maintenance is going to cost him per annum. In a question which is of equal importance to the station engineer and to the manufacturer there should be concreation between the to the manufacturer there should be co-operation between the two. The manufacturer should be prepared to quote a reasonable figure for maintenance. It may very possibly cost him more than this amount, but he is still seeking experience and should be prepared to pay for it. The station engineer on his part is auxious to keep the consumer satisfied. He should, therefore, be prepared to carry out the maintenance on behalf of the manufacturer at practically cost price; but the manufacturer should not expect more than this.

There are still some station engineers who think that the diversity factor of a cooking load is not high. On the other hand, it is sometimes stated that the diversity factor is as high as 20. This figure, however, is based on the maximum possible load of the apparatus, and it would seem more reasonable to take the consumer's maximum as being about 75 per cent. of the maximum possible. Thus the figure of 20 would drop to 15, which means that the load factor of the individual consumer is under 7 per

In the case referred to at the beginning of this paper, the maximum possible load is about 8.5 kW. The average consumption per day (omitting a period of absence in summer) is about 14½ kW. hours, giving a daily load factor of 7.1 per cent. If the working period of 15½ hours per day is taken, the load factor becomes a little over 10 per cent. Since the product of load factor and diversity factor cannot exceed 100, it follows that the diversity factor of this particular type of consumer could not be greater than 10, but it might reach that satisfactory figure. It may well be that the leaves appears the shows the satisfactory figure. be that the larger apparatus shows the smaller diversity factor: but the load factor being higher, the desirable form of load (i.e., 100 per cent. load factor on the distributors) is obtained with a smaller number of consumers. Owing to a lack of appreciation of these principles, people sometimes talk of impossible load factors of over 100 per cent.

The above remarks are supported by records which the author has taken, one of which is reproduced in fig. 4. It is evident from these that the load is well distributed throughout the day, the consumption in any part of the day varies considerably, and the character of the load varies from day to day. Consequently the combined loads of, say, half-a-dozen consumers of this precise type would give a much better curve than any of the curves taken

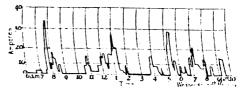

FIG. 4.—TYPICAL DAY COOKING-LOAD CURVE.

individually, because the "Tuesday" of one consumer may be the "Friday" of another. Fig. 5 is the composite or average curve which shows clearly the individual diversity of consumers having the same daily time-table. Actually the diversity would be greater owing to different houses having a different time-table. When, in addition, we remember the diversity of different classes

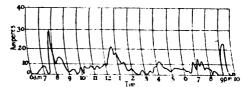

Fig. 5. -- Composite Curve of a Week's Cooking-load RECORDS.

of consumers it becomes evident that the cooking load is one that is very desirable. The lighting peak and the cooking peak do not appear to coincide, and the average load from 6.30 p.m. to 8 p.m. is less than would be expected.

#### DISCUSSION IN LONDON.

Mr. George Wilkinson (Harrogate), who opened the discussion, said the first thing that struck him was the title of the paper; he was unaware that members of the Institution were well acquainted with the subject. He thought that, generally speaking, the supply engineer had been too careful when he initiated new tariffs: commercial people were prepared to take some risk during the early years, but station engineers often fixed their prices on the basis of existing conditions instead of making an estimate of future output and basing the price on that. He had recently altered his own house and installed electrical apparatus throughout, and now own house and installed electrical apparatus throughout, and now used a 12-gallon electric water heater, thermostatically controlled, which gave a supply of hot water at 180° F., night and day, suitable for drinking or washing purposes. This was for a family of six and it required 12'8 units per day, giving a load factor of about 50 per cent. On the question of tariff, if a ½d. per unit was a fair price for a 25 per cent. load factor, surely ½d. was fair for 50 per cent. If he had to start again, he would use a 25-gallon water heater with a small heater, controlled in the same way, thus increasing the load factor. He had found that the water from a coke boiler was unpleasant in taste for drinking, but the way, thus notes and the total factor. He had total that the water from a coke boiler was unpleasant in taste, for drinking, but the water from the electric heater could be used in kettles, &c., and thus saved the use of hot plates. He had experimented with a "set pot" electrically heated, but found radiation losses too expensive. The ordinary wall plugs could be superseded by large switches in the kitchen, with advantage. He considered that the question of maintenance of cooking apparatus was a serious one, and did not think it could yet be recommended without qualification by the engineer; but the apparatus had been greatly improved. His experience was with four cookers, the last one for 18 months, and one hot plate had broken down three times in that period. It would pay the manufacturers to further improve this apparatus, so that it could be recommended as confidently as in the case of modern heaters.

MR. C. H. WORDINGHAM was inclined to think that the station engineer knew too much about electric cooking to adopt it in his own house, and considered that greater reliability was necessary before it could be generally adopted. He had always been surprised at the claims made as to saving in loss in weight of meat by electric cooking; this loss was due to the use of too high temperatures with any form of cooking. The difficulty of econo-mically heating water electrically was a serious drawback, and he urged that they should give up that idea or it might hinder the progress of cooking: they must recognise the limitations. He, personally, did not see the use of 12 gallons of hot water; unlimited quantities were required, and he did not believe that any juggling with tariff would facilitate electric water heating. The author seemed to use the coke stove for keeping things hot and then called it electric cooking; he must pay heavily for his rapid heating, as the KW. Went up and the load factor went down in such a case. He wished to draw their attention to the question of standardising cooking apparatus, which had formed the subject of a vecent leader in the ELECTRICAL REVIEW. The amb Comersonally, did not see the use of 12 gallons of hot water; of a recent leader in the ELECTRICAL REVIEW. The sub-Committee of which he was a member had considered this matter. He felt that plugs must be standardised, but as for cooking apparatus, it was quite a different matter. The makers had been approached,

but there was a great diversity of opinion amongst them, and they were not eager. He could not help thinking that certain things could be standardised in regard to oven sizes and hot-plates, and it would be most helpful if the manufacturers who were present

would give their views.

MR. ALLEN (Wolverhampton) said there appeared to be very few remarks in the paper, which could come from a non-technical consumer. He did not see how the fact of using a large cooker led to a better load factor. In his experience an energy consumption of 1.6 units per head per day was the usual thing for a family of six. The author gave a fearful and awful bill for apparatus, but it was quite abnormal, and he was astonished that he had put it it was quite abnormal, and ne was astonianed that he had put it in. He agreed with his remarks on wood casing and earthing, but it was not his experince that people did not mind paying a lump sum for a cooker. The pilot light was being generally used, but the thermometer was a complication; they had cooked without it for 50 years, and could continue without it. As regarded the saving in weight of meat cooked electrically, he had always understood that it was the better temperature recrulation which was presible. that it was the better temperature regulation which was possible, which led to this saving. The author's suggested earth-rimmed plug might be more dangerous than the ordinary one, and he had not referred to the fixible which had an embedded steel wire, and was now becoming common, nor to C.T.S cable, which was suitable. He agreed that the use of earthed and unearthed apparatus together was dangerous, and to be avoided. The rateable value system of charging was the best understood tariff, and the best ne for introducing electric cooking, in his experience. thought, always au optional tariff, and the author_could probably have had a fist rate if he wanted.

ME. R. S. DOWNE said the point of view of most consumers in regard to electrical cooking was that it must be obtainable on reasonable terms. The various testimonials which he had received were more convincing than the paper. If the author had lived in the Brompton and Kensington area he could have paid 5s. or 7s. 6d. per quarter rental for his installation, fixed and wired, and would have had utensils supplied free, or if he desired to purchase, he would have had to pay £14 for the installation, including wiring, instead of the high sum of £35. Electric cooking would have to be carried out on exactly similar lines to the gas-cooking business all over the country, and in the immediate future an installation would not exceed £10 in cost. He agreed with Mr. Wordingham that electric water heating was too costly, and at his company's restaurant coke fired boilers were MB. R. S. DOWNE said the point of view of most consumers in He agreed with Mr. Wordingham that electric water heating was too costly, and at his company's restaurant coke fired boilers were now used, giving twice the amount of water for 7s. a week as against the electrical cost of £1. He considered that the gas people had prepared the way for electric cooking, and it would be adopted on an extensive scale in the near future. In his area they had about 100 cooking installations installed (during the past three years), and the progress was becoming rapid owing to personal recommendation. There was no doubt about there being in practice a considerable saving in shrinkage of meat by electrical cooking. As the result of inquiry he was informed that with the coke-fired ovens at Cadby Hall (Messrs, J. Lyons & Son's headquarters), there was a loss in weight of meat cooked over head of 30 per cent. A test on a large scale of electric cooking showed only 18 per cent. loss, representing a saving of some 10s. showed only 18 per cent. loes, representing a saving of some 10s, worth of meat in that case as compared with the ordinary process. The average consumption of energy per cooker in his area was some 2,500 units a year; or 1½ units a head per day for five persons. It was estimated that at least 1,200 consumers in the area could adopt electric cooking, and taking an installation at 5 kw, the extra 6,000 kw. of load would only come on to the peak to the extent of 1,000 kw.

ME. GROGAN thought it possible that the author had been too much in the kitchen judging by the excessive energy consumption; he did not agree that the large consumer was better than the smaller one, as regards the cooking load, as the latter had the batter diversity factor and load factor. He was glad the author had not adopted electrical water heating, as the result would have been awful; but the electrical method was satisfactory as regarded been awful; but the electrical method was satisfactory as regarded convenience and if a small quantity of water was sufficient. From his experience, a family of five should require from 1,500 to 2,500 units per annum for cooking and allowing the author another 1,000 units, or 3,500 units, this should be sufficient for seven people, so that his energy consumption was much too high. He knew of a Manchester household of similar size which took 65 units per week for cooking, as against the author's 110 units. He asked, was this paper going to help electric cooking? He him-He asked, was this paper going to help electric cooking? He himself looked upon it as a murderous submarine attack on the splendid progress made in recent years. The author had paid extravagantly for his installation; why should he inflate the bill by the cost of the coke boiler? He had apparently mentioned hiring of apparatus as an afterthought; there were some 30 or 40 towns hiring out electric cookers, and that was the only way to do the business.

Mr. Duncan Watson said the paper gave them the opportunity to correct the views put forward. His sympathy was with the engineer who was unable to offer a suitable tariff for cooking. He had heard that much more efficient apparatus was to be introduced

had heard that much more efficient apparatus was to be introduced shortly; at present maintenance was rather a serious matter.

MR. HAYDN HARRISON had not found the p per to have much reference to the "consumer," as usually understood. As a user of electric cooking, he had turned up his bills for gas, coal and of electric cooking, he had turned up his bills for gas, coal and electricity for the past five years, during which period he had adopted electric instead of gas cooking, and it was not at all easy to tell when he changed over. His district was supplied by a company which did not encourage electric cooking, and charged 1½d, par unit for the supply and 5d, per unit for lighting, but despite this high price and the fact that gas was only 1e. 93, per 1,000 cb. ft. the change over had not made any appreciable addition to the cost. He was afraid the paper would not be rightly read, and that it would be taken to mean that the author had made a loss

of £9 after spending £45 on apparatus.

ME. W. M. MOBDEY suggested that if the principle of the thermos flask could be adapted in the electric oven, a considerable saving in energy would result once the right temperature had been

MR. PINKNEY said the author's energy consumption for cooking was very high; in his own family 1.3 units per head per day were required over the first period of six months, and he was convinced this would drop to 1 unit or less, yet the author took 2 units with a "careful" cook. He was afraid the thermometer would not be used, although it would be advantageous if it

PROF. MORRIS said it was important that electric cookers should PROF. MORRIS said it was important that electric cookers should be hired, as apparatus suitable in one area might be unsuitable in an adjoining one, if the householder moved. He agreed that electric water heating was best left alone for the present, and that attention should be concentrated on cooking. He had found the cost of a coke boiler to be 3d. a day for a family of five or six and this could not be touched electrically. The same family required 1½ units per head per day for cooking. A big scale thermometer would be a useful accessory if it could be mounted with the switches on the wall. He found that cocks did not understand what shocks were.

understand what shocks were

MR. A. H. SEABROOK felt that it was a case of "saving us from our friends"; he strongly deprecated the publication of such doubt-ful results. The large cooking consumer was infinitely worse than the small one in the matter of load factor, and in the matter of cooking load he would prefer, say, liford to Marylebone. In Marylebone there were one or two consumers using electric water heating; they were satisfied with the cost and that was all that mattered. The initial cost of the author's installation was utterly ridiculous; he (the speaker) could not find a householder who would buy a cooker—the hiring practice was too firmly established. There was no more sense in running a cooker on a single fuse, than there would be in running, say, a small town in the same way. He found that thermometers were soon taken off cookers, and that the Scott Ram hand-shield plug was quite satisfactory. He thought that the earthing of cooking apparatus was compulsory. The author's curves showed a non-peak load, with the largest demand in the morning. He mentioned that Mesers. Selfridge had now placed an order for an installation forstaff cooking, which would be the largest in the world. He found that thermometers were soon taken off

MR. NICHOLS MOORE said the author's paper should indicate to engineers what they had to deal with. He considered it futile to make random statements as to the saving in weight of meat by electric cooking; the author's figures showed a saving, but they were not cooking joints all the week, and the saving in £ s. d. did not amount to a great deal. He found in his own case that a "domes-

tio" tariff with a secondary rate of \( \frac{1}{2} \)d. per unit showed a slight saving in cost over flat-rate charges.

MB. GILLOTT said he understood that the American navy had firing with the bottom heat. In his own case, with seven in the family, it required 97 unit per head per day for electric cooking. Why had the author debited all the fixed charges to electric cooking.

why had the author decreed an energy and country and ing? This seemed unfair,

Mr. F. C. RAPHAEL said the author had made the mistake of generalising from a particular case, and he was afraid much too great publicity would be given to his unfortunate experiments. The author's experiments on flexible had been forestalled by work

MR. COOPER replied very briefly, owing to the lateness of the hour; he felt justified in his paper in view of the contradictory nature of the discussion. He had regarded it as an optimistic paper! He agreed that electric water hating was very convenient.

#### ELECTRICITY APPLIED TO MINING.

BY C. P. SPARKS, M.I.E.E.

(Abstract of paper read before the Institution of Electrical Engineers, February 25th, 1915.)

(Continued from page 378.)

A winder driven by a direct-coupled induction motor is erected at the Aberewinhoi Colliery. The duty for which it was designed when fitted with a tail rope of equal weight to the winding rope is as follows:-

Depth of shaft ... ... Output of coal per hour Net load of coal per wind 240 yards. 180 tons. 50 cwt. Number of trains per wind ... 2
Time of wind ... ... ... 35 sec.
Time of each complete cycle 45 sec.

The 3-phase motor is wound for 3,000 volts working pressure and has its rotor mounted on a continuation of the drum shaft. The continuous rating of the motor is 375 B.H.P., the maximum horse-power developed during the acceleration period being 700, with a power factor of 0.75. A liquid controller is provided for starting and regulating the motor and is interlocked electrically with the oil-break main and change-over switches for reversing the motor. The resistance in the rotor circuit is determined by the height of the liquid, which is varied by a sluice valve connected to the controller. The liquid is cooled by pipes in which water is circulated, and is pumped from a storage tank in the base of the controller by a small electrically-driven centrifugal pump. The winder is controlled by one lever which is connected to the main stator switch, the controller, and the brake engine. The controller can maintain a minimum motor speed of 2.5

The controller can maintain a minimum motor speed of 2.5 r.p.m. with one-tenth normal torque for 15 minutes for rope

examination, etc.

The drum brakes are of the post type, and are weight-loaded air-operated with the Whitmore patent self-adjusting and variable-load appliances, by which the driver can apply

and variable-load appliances, by which the driver can apply any desired load upon the brake according to the amount that the foot lever is pressed down.

The air supply for the brake cylinder is provided by an electrically-driven compressor set. This set consists of a compressor direct-coupled to a 3-phase motor with automatic starting and stopping, controlled by the pressure in the receiver, the working value of which is 60 lb. per square inch.

Should the power supply fail either through failure of the main supply or the operation of the overload main-switch relays, the brakes are automatically applied and the winder drum is brought to rest.

A dial depth-indicator is used, with which is incorporated the overwinding gear. The latter in case of an overwind applies

A dial depth-indicator is used, with which is incorporated the overwinding gear. The latter in case of an overwind applies the brakes and cuts off current from the winding motor.

This winder has been in satisfactory operation for the last six years. The "peak" due to the sudden application of a load of 750 K.V.A. every 45 or 50 seconds is satisfactorily dealt with at the power station by the Tirrill regulator. The number of units per ton of coal wound without a balance rope, is 1.6 when winding 25 cwt. of coal.

Pumping.—The steam plant has been supplemented or displaced by single-lift centrifugal pumps, and in place of pump-

size of the pumping plant, two 17½-in. fans, one being in reserve, are erected in the passage way leading to the up-cast shaft and discharging into it; incoming air is brought through a special heading driven into the down-cast shaft. An air filter consisting of cloth stretched on wooden frames is erected at the incoming end of the pump room, and suitable dampers are provided at each motor for controlling the supply of air. The system of forced lubrication employed for the pumps and motors consists of oil tanks fitted with submerged "spurwheel" pumps, chain-driven by small 3-phase motors mounted on the covers of the tanks and supplying oil to the various bearings. Each pump is fitted with an oil filter which can be withdrawn and cleaned while the pump is in action.

The overall efficiency of the above set tested at full duty

withdrawn and cleaned while the pump is in action.

The overall efficiency of the above set tested at full duty was 71.9 per cent.

Ventilation.—Up to a few years ago the general colliery practice was to use low-speed fans; latterly a considerable number of centrifugal high-speed fans have been employed.

All the principal fans of the Powell Duffryn Co. have duplicate motors as a stand-by to allow for cleaning and repairs. These fans are driven by induction motors, and in order to give flexibility in the volume of air the fans are rope-driven, to allow the pulley ratio to be varied.

or allow the pulley ratio to be varied.

At the new Britannia Colliery, the fan employed is designed for the full air output for ventilating the workings when the latter are fully opened out, but until this time has arrived it will run at speeds to suit the development. The electrical equipment consists of a rotary converter and continuous-current motor, the latter being direct coupled to the fan shaft. Speed variation is obtained by hand regulation of the field rheostat. The stand-by motor in this case is of the induction type, the fan being rope-driven.

Compressors.—Although the efficiency in transmission and conversion is low, compared with electricity, compressed air is largely used underground where danger may arise from dust, gas, or falls, for all small power drives. The Powell Duffryn Co. erect the main compressor plant in the winder house so that it can surply all conversates the transmission. that it can supply all requirements, the separate air systems

PUMP DATA.

... 1,660 ft.

60,000 gallons per hour. Sulzer 8-stage, 1,480 r.p.m. Capacity Speed and Type ...

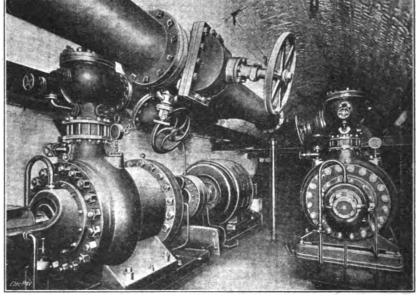

Fig. 7.—Pumping Station, Elliot Pit, Showing Westinghouse-Sulzer Pumps.

ing continuously, the main pumping is now confined at the Elliot Pit to 8-12 hours out of the 24 by enlarging the lodge Elliot Pit to 8-12 hours out of the 24 by enlarging the lodge rooms, the pumping in the other valleys being confined where possible to the night shift. This has a marked effect on the lead factor of the power houses, and in the Rhymney Valley it has provided the continuous load necessary for the economical use of gas-engine plant.

The largest pumping station is at Elliot Pit, the pump room being situated at the foot of the up-cast shaft and containing three Westinghouse-Sulzer centrifugal pumping sets; two of these are driven by 950 B.H.P. 3-phase motors, and the third by a 1,000 B.H.P. motor, the following being the respective duties:—

duties :-

	950 в.н.р.	1,000 в.н.р.
Gallons per hour	81,000	87,000
Head in ft. (manometric)	1,690	1,690
Full-load r.p.m	1,475	1.475

The 1,000-B.H.P. pump is of Messrs. Sulzer's 6-stage type with special cast-iron casing and bronze impeller and guide wheels, and the makers' patent balance-disk method of taking up end thrust. The motor is of the slip-ring rotor type with liquid starter, the stator being built in a turbo-alternator frame. The windings are designed to give a temperature rise not exceeding 35 degrees C. above the inlet temperature of the air which passes through the pump room at the rate of the air which passes through the pump room at the rate of 10,000 cubic feet per minute.

Owing to the confined nature of the pump room and the

being interconnected so as to reduce the percentage of reserve

As the air requirements are intermittent it is desirable to run the electrically-driven compressor at a variable speed. Large variable-speed compressors are at present only operated

by continuous-current motors.

The compressing plant at Britannia Pit consists of three electrically-driven compressors, two running at constant speed driven by induction motors:-

Cubic feet of free air per min. ... 3,500 2,500 ••• Motor r.p.m. 243 Motor r.p.m. ... ... Brake horse-power ... ... •••

Haulages.—Owing to the intermittent nature of haulage loads, the necessity for high torque at starting, and the tendency of all haulages to be used together towards the end of the shift, this load is one of the most costly to supply unless a large number of haulages are worked from the same power house. With induction-motor drive the speed is nearly con-

stant, consequently the power demand is proportionately increased on gradients, thus decreasing the already poor load factor with this class of load. Owing to the position of haulages it is undesirable to employ continuous-current motors, which involve with an alternating-current supply a special

which involve with an alternating-current supply a special converting plant.

The usual form of drive is single-reduction gearing for the larger powers when room can be safely provided, and double-reduction gear for the smaller haulages or when space is

limited.

The original controllers were of the oil-immersed drum type These Where with contactors controlling the metallic resistances. These were not only costly but occupied considerable space. Where water is available all larger controllers are now of the liquid

water is available all larger controllers are now of the liquid type.

The liquid controllers consist of a tank or tanks in the bottom of which are mounted contacts connected to the rotor slip-rings. Corresponding movable contacts are carried on vertical rods actuated by a lever or by a hand wheel, the resistance in circuit being proportional to the distance apart of the fixed and moving electrodes in the electrolyte. The stator reversing-switches are fixed in the framework carrying the tank and are mechanically connected to the lever or hand wheel operating the electrodes. The liquid is cooled by pipes through which water is circulated.

The chief advantages of the liquid type of controller are the finer adjustment of the speed, especially at starting when taking up slack on the rope and shackles, and its simplicity of design, resulting in fewer working parts and greater ease of inspection. The principal disadvantage is the necessity for a supply of cooling water. The latter difficulty can be overcome where no water is available by fitting a system of radiator cooling pipes and a small motor-driven centrifugal pump. While this method works satisfactorily, it adds considerably to the first cost.

Owing to the heavy duty imposed on reversing switches of

Owing to the heavy duty imposed on reversing switches of Owing to the heavy duty imposed on reversing switches of both types of controllers a special design is called for, as the frequency of operation under conditions of maximum load is much higher than that required from any other switch. To prevent overheating and formation of carbon deposit it has been found necessary to design these switches on generous lines, with an increased area of contact and a big head of oil as compared with standard switches of the same rating.

The smaller motors up to 30 B.H.P. used for driving the various auxiliaries on the surface are of the standard protected 3-phase type, wound for 500 volts. The majority of them have slip-ring rotors with liquid resistances for starting, this type of rotor being preferable to the squirrel-cage type, on account of the reduced switchgear maintenance.

#### TRANSMISSION SYSTEM.

Experience has proved the reliability of overhead transmission with bare conductors for colliery supply. Apart from the saving in first cost, the main risk through the use of cables is avoided, namely, subsidence.

To secure safety it is advisable to screen the overhead conductors at all points where they cross traffic. The efficiency of screening is dependent on reliable earthing, which is best secured by a continuous, stranded earth-wire of substantial section, effectually earthed at each end and connected to intermediate earth-plates every 300 or 400 yards. In order to minimise risk, all main conductors round the pit head should be run as armoured cable.

minimise risk, all main conductors round the pit head should be run as armoured cable.

The overhead system used by the Powell Duffryn Company in the Aberaman Valley was described in the previous paper.*

The following modifications have been made to meet the developments in the last nine years:—

All collieries in the Aberdare Valley are now supplied by a system of 3,000-volt ring mains, protected on the Merz-Price system.

system.

system.

The section of the main feeders of hard-drawn copper has been increased to 0.15 sq. in. (19/12 S.W.G.), the wires being grouped in a triangle, for single circuits 3 ft. 6 in. vertically and 4 ft. 6 in. horizontally; with double circuits the conductors are carried on three cross-arms, the circuits being spaced 4 ft. horizontally and the phases 3 ft. vertically apart.

The pilot wires for the Merz-Price system consist of either one or two 3-core 7/21 S.W.G. paper-insulated lead-covered cables, suspended from galvanized steel catenary wire, 7/14 S.W.G., by raw-hide suspenders, these conductors being carried at the extremity of a fourth cross-arm fixed at about 4 ft. below the main conductors. below the main conductors.

The average length of span is 100 ft.

Little depreciation is noticeable at the base of the creesoted

Little depreciation is noticeable at the base of the creosoted wood poles, which have been erected over 10 years.

The overhead wires radiating from the Middle Duffryn power station have been displaced by 3-core paper-insulated lead-covered armoured cables to a point well clear of the power station, washery, and railways. The overhead wires branch from brick towers, in which the choking coils and horn-gap lightning arresters with liquid resistances are placed.

The Rhymney Valley 10,000-volt transmission lines run from Penallta to Bargoed, a distance of 3½ miles. Duplicate circuits are run between Penallta and Pengam on the same "A" and "H" poles, and between Pengam and Bargoed on separate poles, the two pole lines being about 30 ft. apart. This allows the Britannia Colliery, which is completely electrified, to be supplied from either of two power houses by

two sets of duplicate transmission lines, grouped on three independent pole lines

independent pole lines.

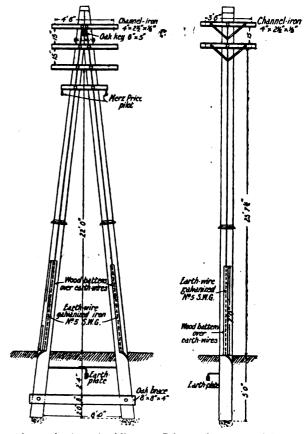

Wood poles are employed 36 ft. long, the maximum diameter at the base being 11½ in. and at the top 7½ in., and the pole being buried in the ground 5 to 6 ft.

The conductors are hard-drawn copper, 0.25 sq. in. section (37/13 S.W.G.). The phases are spaced vertically above one another, 15 in. apart, the two sets of transmission lines between Penallta and Pengam being 4 ft. 6 in. apart (figs. 8 and 9), and the average span being 100 ft.

The insulators of the double-petticoat pin type are carried on three channel irons of section 4 in. × 2½ in. bolted to the poles, each insulator being subjected to a test pressure of 75,000 volts under standard precipitation, and a pressure of 75,000 volts when dry.

75,000 volts when dry.

Each circuit is protected on the Merz-Price system, as at Aberdare, the catenary wires acting as the earth connection.

A pole carrying two sets of lines. FIG. 8.-10,000-VOLT TRANS-MISSION LINES.

Pole carrying one set of lines. FIG. 9.-10,000-VOLT TRANS-MISSION LINES.

The overhead lines are connected to the generating station and

sub-stations by 3-core paper-insulated lead-covered and armoured cables 250 yards in length.

Two duplicate sets of 0.2 sq. in. hard-drawn copper (37/0.082 S.W.G.) 3,000-volt lines connect Bargoed with Elliot Pit and New Tredegar. These are also protected on the Merz-Price system. As the demand increases, the pressure on these lines will be rejected to 10,000 volts.

system. As the demand increases, the pressure on these lines will be raised to 10,000 volts.

The distance between the Middle Duffryn power station and the new Britannia Colliery is approximately nine miles. The transmission line will be constructed for a working pressure of 30,000 volts. In the first instance, however, the line will be worked at 20,000 volts, supplied through three 2,200-k.v.a. single-phase oil-insulated water-cooled step-up transformers connected so as to give 3,000 volts mesh to 30,000 volts star, and 30,000 volts star to 10,000 volts mesh. When working at 20,000 volts the transformers will be connected mesh to mesh, the ratio being adjusted when connected mesh to star by cutting out part of the neutral ends of the star winding.

The transmission line will be controlled by switchgear on the 3,000 and 10,000-volt systems, the transformers being connected direct to the transmission lines through isolating switches.

switches

When working with transformers mesh to mesh, supplementary star transformers with the neutral earthed will be used to operate the protective system, the Merz-Hunter split-phase control being used, and the switchgear being actuated in the event of a line fault by balanced transformers connected in series with the split-phase conductors. Time-limit overload relays will be used to protect the 3,000 and 10,000-volt systems.

The power factor and the pressure drop on the transmission line when supplying from one end will be controlled by hand-regulated static boosters star-connected on the 3,000-volt system at Middle Duffryn.

The transmission lines will consist of six 0.073 sq. in. stranded conductors, each comprising 7/11 S.W.G. hard-drawn

^{*} See Elec. Rev. April 20th, 1906.

copped wires arranged on normal spans with the phases 5 ft. apart vertically, the split phases being at 4 ft. horizontal

The conductors will be carried on pin-type insulators mounted on three channel irons, these being protected by insulated sleeves so as to prevent birds operating the protective gear. Steel poles will be used, and the average length of span on straight runs will be 120 yards. For railway and road crossings a special construction will be employed, with double

crossings a special construction will be employed, with double insulators and heavy-section screening.

A continuous earth-wire of 7/13 S.W.G. hard-drawn copper will connect the metal-work of the entire system, each transmission pole having a galvanised iron earth-plate electrically connected to the main structure of the pole.

The end connections for the transmission line will consist at each end of not less than 300 yards of 0.1 sq. in. split-phase paper-insulated lead-covered double-wire-armoured cable, the armouring being connected to the continuous earth-wire at each end and to the main earth connections at the Middle Duffryn power station and Britannia Collieries.

Fig. 5 (p. 377) shows the route of the 20,000-volt transmission line. With the completion of the latter the Britannia Colliery will be fed from three power houses by three independent routes. The annual load factor of the entire undertaking will be as high as 55 to 60 per cent., while the reserve plant in either valley will be available for the whole undertaking.

(To be continued.)

#### CORRESPONDENCE.

ceived by us after 5 P.M. ON TUESDAY cann ot appear until the following week. Correspondents should forward their communi-cations at the earliest possible moment. No letter can be published unless we have the writer's name and address in our possession.

#### Consulting "Engineers."

Concerning consulting engineers and others mentioned by "Station Engineer" and "Ero," may I remind your readers that as far back as the Victorian Era your Correspondence columns found space for the discussion of the status of the hangers-on who impede the positive achievements of our industry, even now that it is demonstrated that the workers have outrun them in their own sphere?

There are works and factory engineers, with more electrical schemes on hand (in addition to their own routine work) than may be found in any of the top-floor back offices of the consultants. Men of the line prefer the lead of these electrically-equipped mechanics to the buffoonery of the so-called consultants whose quantities and specifications are redolent of 1885, and whose initiative is as obsolete as are their methods of measuring up a job of the looped-in type, which they often do not understand. Before me now are the specifications and quantities for a job just completed without them, they being ignored for the following reasons:—

The much "stock-phrased" specifications ridiculously divorced modern practice from the plans and quantities.

The schedule becoming useless by the discovery to the consultant and his client alike that the lighting of areas and the adaptation of power were matters nowadays better understood by the worker in practice than it was conceived by the consultant whose mental attitude towards the industry harked

adaptation of power were matters nowadays better understood by the worker in practice than it was conceived by the consultant whose mental attitude towards the industry harked back to the days of the tree system and two-pole machines.

During the last three months the writer has had to return to stores huge quantities ridiculously unnecessary, and to requisition other quantities applicable by the rules and regulations but not provided for. Even since December last we have had to refuse point-blank to run mains in the same conduits carrying circuit wires, as directed—this on a split 200-volt D.O. system.

We have removed crossings shoved up into ceilings to obtain flat ceiling effects, and prevented the use of fibre in the crossings of casings, etc., none of which was objected to by a consultant (of too long standing).

We have fought stiff wordy battles to persuade a "specialist" that H.V. I.C. distributing boxes, etc., ought not to be fixed on the wood surfaces of flue hoists where brick or stone walls were available.

walls were available.

We have been "eccentric" enough to demonstrate the unwisdom of arranging a 400-volt power net-work upon the same panel as 200-volt lighting circuits, as well as being wicked enough to disagree to the fixing of pairs of s.p. lighting switches on the same base block and connected to dis-boards

switches on the same base block and connected to dis-boards on opposite sides of three wires.

And, to be brief—were it not for the law of libel, much more could be said; it is sufficient, however, that there are men directing matters electrical who, being unable to do what they know how to do, are solacing their own mediocrity by occasionally escaping from their top-floor back offices to harass an industry which is forging ahead in spite of them. "Station Engineer" as well as "Ero" need be careful lest they, too might get elhowed out of the way like they, too, might get elbowed out of the way like

J. B.

#### The Government Electric Power Station at Bangkok.

In a letter dated January 4th, 1915, your correspondent H.E.F." made certain comments in regard to this plant which, in fairness to all the parties connected with it, stand

which, in fairness to all the parties connected with it, stand in need of some correction.

The specifications upon which the tenders were submitted were drawn up by the Siamese Government's electrical engineer, Mr. Shaw, and invitations to tender upon a definite size of plant were issued to all the well-known electrical manufacturing concerns in Great Britain, Germany and America. These facts will dispose of your correspondent's suggestion that German engineers were responsible for the size of power station and will show that in the competition for the contract, all firms, regardless of their nationality, were placed on the same footing.

It may be of interest to your readers, and satisfying in

on the same footing.

It may be of interest to your readers, and satisfying in some measure to the patriotism of your correspondent, who fears for British enterprise, to point out that while it is true that the A.E.G. secured the contract, their tenders were prepared by British engineers under the supervision of the Fritish manager of the A.E.G.'s foreign department, and British enterprise sent out a British engineer to Siam to carry out negotiations in regard to the A.E.G.'s tender, which resulted in their securing the contract.

It is not correct as your correspondent states that the price

It is not correct, as your correspondent states, that the price quoted by the A.E.G. was much below that of all other firms competing; neither is it correct to suggest that the final cost quoted by the A.E.G. was much below that of all other firms competing; neither is it correct to suggest that the final cost of the plant has been increased by charging the Government with a large number of extras. If the total cost of the power station has exceeded the original Government estimate, it is partly due to unforeseen difficulties in regard to the erection of the buildings and extensions to the original scheme. The erection of the power station and its operation during the guarantee period have been carried out under the supervision of British engineers, so that German brains have had very little to do with the inception and carrying out of this scheme. This statement is due to the British engineers engaged upon it. When it is added that, although the contract was carried out by the A.E.G., who built the steam turbo-generators, the boiler-house plant was supplied by Messrs. Babcock & Wilox. Ltd., and the switchgear and transformers by the British Thomson-Houston Co., the history of this plant may be judged in its right light. There has been no dispute, as your correspondent suggests, between the parties concerned in regard to the boiler furnaces. There was a natural desire on the part of the Government officials, the main contractors, and the boiler makers to utilise all the experience obtained in other boiler plants in Bangkok with paddy-husk furnaces, and this led to certain modifications in the original design, which the results fully justified.

In a recent letter from Bangkok informing the contractors

led to certain modifications in the original design, which the results fully justified.

In a recent letter from Bangkok informing the contractors of the successful conclusion of the tests, it is stated that as regards the boilers, the trouble taken to secure success has been fully justified, as the paddy-husk consumption has been reduced to a figure which has surprised the officials represented at the tests; moreover, with the new furnaces, an almost smokeless chimney has been obtained.

While the size of the plant may be too great for present demands, Mr. Shaw's faith in the growth of electrical enterprise in Bangkok will be justified sooner or later. Want of faith in the possibilities of electrical development has perhaps been one of the causes of the slower growth of the electrical industry in England than in Germany and America.

Bangkok.

Bangkok.

[The fact that Mr. Shaw has not replied to the comments above-mentioned is due to his absence on active service as an officer in the armoured-car division.—Eds. Elec. Rev.]

#### Government Control of Factories.

Everyone has noticed the number of ridiculous statements which have been appearing in the Press recently and which has for its culminating feature the control of factories by the Government. For instance, in the House of Commons last week, it was stated there were no firms "not already engaged on Government work" in this country who could make similar goods to Siemens. We have recently, on two separate occasions, made applications to the War Office to be placed on their list of contractors, but owing to the fact that fifteen years ago one of the officials of this company offered a couple of theatre tickets to a War Office official, for this serious offence we were struck off the list. We have only one official now working for this company who was with them at the time. The directors are a totally different body of gentlemen, and yet the War Office cannot see its way clear to put us on their list. This is surely visiting the sins of the fathers, etc. The peculiar part of the whole business is that about 75 per cent. of our present output is war material through sub-contractors. We have even had a visit from one of the Government officials asking us how many men we could spare the War Office for machining ammunition, etc., and yet, in spite of all this, we are not respectable enough to be on the War Office list. It makes one feel inclined to side with those who are working for a business Government.

Walsall Electrical Co., Ltd., V. Delebecque, Works Manager

Walsall, March 12th, 1915.

#### Coke Fuel for Steam Raising.

Our attention has been called to the letter signed "Engineer and Fuel Expert, London Coke Commission," who, we believe, is Mr. Nickoll (of the Gas Light & Coke Co.). The remarks he attributes to Mr. Horace Boot are incorrect, inasmuch as what Mr. Boot said at the meeting of the South Metropolitan Electric Light & Power Co. was, as correctly reported in your previous issue, that if Mr. Bowden thought he was going to get the same output from the boilers by using coke breeze as he previously could when using coal, it could only be achieved by forcing the boilers, which forcing seriously diminished the life of same. On the other hand, no doubt, by increasing the number of boilers and burning coke breeze at about 6s. or 8s. per ton, economy can be gained, as we have on several occasions intimated to our clientele. We venture to think these remarks will be confirmed by every boiler user who has tried various classes of fuel.

Horace Boot & Partners. Our attention has been called to the letter signed "Engineer

#### Showroom Windows.

The writer in your issue of last week, under the heading of "Showroom Windows," has raised our expectations, and I hope will be able to fulfil them.

A good number of supply managers are interested in this question of how to dress showroom windows. The writer states that with irons, kettles, toasters, radiators, cookers,

As the writer claims to have had a very large amount of practical experience, it would also be of assistance if he could give the exact cost of dressing each window, exclusive of the

actual electrical apparatus.

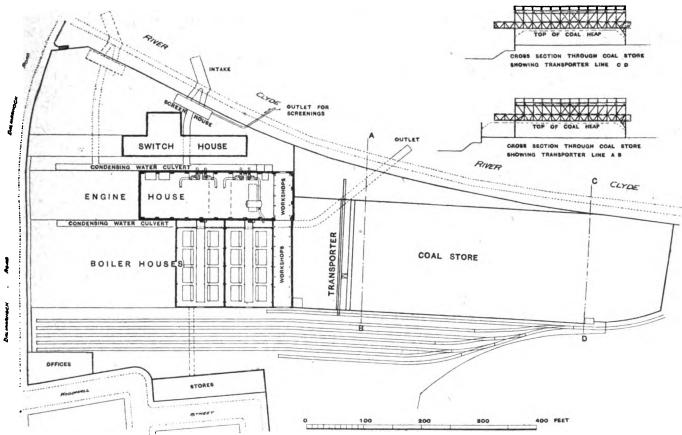

If he gives something of this kind it will certainly be practical, at least.

Electric Supply.

#### GLASGOW FLECTRICITY WORKS.

MR. W. W. LACKIE, Chief Engineer to the Glasgow Town Council's Electricity Department, has issued to the members of the Electricity Committee descriptive notes on the new works at Dalmarnock Bridge, of which the following is an

The site of the Dalmarnock Road electricity works has a total area of 13th acres, the total cost being £27,112, and is admirably a supply of condensing water is area of 13½ acres, the total cost being £27,112, and is admirably suited for its purpose. An ample supply of condensing water is obtainable from the River Clyde, and railway sidings are already laid on to the site. The first portion of the works, which is now under construction, consists of a water intake, a screening house, two water culverts (one for the inlet water and one for the outlet water), switch house, turbine room (75 ft. × 240 ft.), two boiler houses (each 150 ft. × 84 ft.), workshop and store, and a complete coal-handling plant capable of dealing with 100 tons of coal per hour. Contracts were placed for the excavation of the ground in April, 1914,

SKETCH PLAN OF THE NEW GLASGOW ELECTRICITY WORKS AND SITE, AT DALMARNOCK BRIDGE.

"nothing should be easier than to make an attractive display," and he finishes the article by whetting our appetite for "suggestions."

The showroom window is perhaps one of the most difficult things to deal with, that is, assuming it is a fairly large shop window. To get a continuous series of displays sufficiently attractive "for nobody to pass the shop without glancing in," as your writer mentions requires a good deal of invention as your writer mentions, requires a good deal of invention and ingenuity, when novelty has to be obtained year after However, your writer comes along in optimistic style, and I am sure a good many readers will be anxiously awaiting any useful hints.

May I suggest that, as we have had in technical journals quite a plethora of vague generalities, your writer should put his suggestions in a series of cut and dried specifications for

his suggestions in a series of cut and dried specifications for a series of windows lasting over a year?

By specification I mean, not a general hint, but a detailed list of the exact apparatus to be put into the window, together with any ornamentation and any special showcards, sufficiently in detail for the specification to be put into the hands of any showroom assistant, so that by following it literally he could obtain exactly the effect that the writer would recommend. The writer should assume that there is a large shop window absolutely blank—floor, ceiling and sides.

and subsequently, in August, for the water channels and concrete foundations. These contracts amount to a total of £48,000. The contract for the coal-handling plant has also been placed, and the cost of this portion of the work amounts to £24,800. Offers will shortly be asked for the first portion of the buildings, and specifications for the first instalment of the plant are practically ready. This plant will consist of two 10,000-kw. turbines and one 15,000-kw. turbine, coupled direct to A.C. generators. There will also be three 1,000-kw. turbo-sets for driving auxiliary machinery; and all the necessary condensing plant and circulating pumps. It is proposed to continue installing plant units of 15,000 kw. as the demand increases, but units of 30,000 kw. can be installed if found desirable. The ultimate capacity of the Dalmarnock works will be at least 140,000 kw. It is intended to transmit electricity from the works at a pressure of 20,000 volts (three-phase alternating, 25 periods per second) to existing distributing centres at Port Dundas, St. Andrew's Cross, Govan, and Partick The energy will be transformed there from 20,000 to 6,500 volts, and distributed at this pressure to existing sub-stations where again it will be transformed to low-pressure current for the general supply throughout the city. Ducts are now being laid from the works to Cathedral Street sub-station, and the existing spare ducts from Cathedral and subsequently, in August, for the water channels and con-

Street to Port Dundas will be used for continuing the supply Street to Port Dundas will be used for continuing the supply to Port Dundas. Ducts will require to be laid from Dalmarnock works to the existing sub-station in French Street, a distance of 1,200 yards; spare ducts already exist running from French Street sub-station to St. Andrew's Cross works. Ducts will require to be laid from St. Andrew's Cross works. Govan immediately, and later on additional mains from Port Dundas to Partick. It is hoped that the first part of Dalmarnock works will be ready to deliver energy at the beginning of the winter of 1916-17.

#### FOREIGN AND COLONIAL TARIFFS ON ELECTRICAL GOODS.

RUSSIA.—The Board of Trade have received a translation of an article published in the January number of the monthly organ of the Moscow factory owners and manufacturers giving organ of the Moscow factory owners and manufacturers giving particulars of certain projected modifications of the Russian Customs Tariff which, it is understood, have been under the consideration of the Russian Government. H.M. Ambassador at Petrograd, in forwarding the translation, states that the information furnished in this article is in no way official, but is probably substantially correct. It appears that the proposals for tariff modification in their latest and revised form include the following:—

posals for tariff modification in their latest and revised form include the following:—

(1) The "Conventional" (i.e., Treaty) rates of duty resulting from the Russian Commercial Treaties with Germany and Austria are to be abrogated, and the goods covered by those rates are to be dutiable at the "General" Rates (i.e., higher), rates of duty increased by 10 per cent. (except as regards certain goods mentioned, of which glassware is probably the only one of interest to the electrical trade, the duty on which is to be increased by about 30 per cent.).

(2) No change is to be made as regards goods the duties on which are fixed by the Russian Commercial Treaties with France, Italy and Portugal. These duties are also applicable to British goods.

to British goods.

(3) All other goods and those other than certain named, but not of interest to the electrical trade, are to pay the existing "General" tariff rates of duty increased by 10 per cent.

The effect of these alterations on British goods is not yet quite clear from the details available, but the Board of Trade promise to publish in due course a translation of the tariff showing in detail the effect of these proposals. Meantime, it would seem that, with the exception of goods covered by the Treaties with France, Italy and Portugal, British goods will still be dutiable at the same rate as German goods, and that the duties in both cases will be considerably higher than heretofore.

#### THE WAR AND ELECTRICITY SUPPLY EXTENSIONS.

In a leaderette in our last issue we ventured to sound a note of warning to municipal electricity supply committees, respecting the necessity for husbanding their resources when subjected to the annual temptation to utilise surpluses in relief of local rates. This is only one of the many important matters that electricity supply authorities are compelled to consider, consequent upon the prolonged duration of the war and the national financial problems entailed thereby. Students of our news pages will have noticed during the last few weeks that electricity supply engineers are being required to hold up their plant and mains extension schemes, and the Government Departments responsible for the control of municipal and financial policy have indicated that not only in new provisional orders granted this year will there be a clause inserted prohibiting expenditure upon such schemes during the war, but also existing works will not be allowed to spend capital upon new plant unless it can be proved beyond question that national needs in war time make such a course imperatively necessary, and, in brief, if new consumers cannot be served from existing facilities then they "must wait" until peace is restored.

Electricity authorities thus find themselves in a position such as they have never occupied before, and one that was never anticipated. The matter may not be one of immediately serious concern to manufacturers who are chock-ablock with Government war contracts, and after the war there may be a rush of works extensions orders, but the position is one of both immediate and serious concern to the municipal electrical engineer and his Committee, and there will be many anxious periods and a variety of new problems arising from it.

It will be remembered that the Treasury has refused to allow the L.C.C. to grant loans amounting to £28,000 to Borough Councils for electricity extensions, paving, &c. The Treasury has written to the Council pointing out that it is desirable that capital expenditure should be restricted to the narrowest possible limits, and that the approval of the Treasury is now necessary for all fresh borrowings. This is particularly serious news for those undertakings that have allowed themselves a small reserve of plant, though for several months it has been clear that all avoidable capital expenditure would have to be postponed till after the war. The normal increase of business in most localities necessitates the constant provision of new plant, and there is also the need for replacement of plant that becomes obsolete. The latter item is one of those that would naturally be deferred, even though the increasing cost of various stores might have given greater relative importance to the installation of more economical plant. Doubtless a sympathetic eye will be turned to the many undertakings whose demand has increased by reason of the extra power requirements of

[425]

factories that are engaged on war contracts. The general desire will be to avoid doing anything that will embarrass the Government at the present time, nevertheless it will not be without regret that the supply station man will see himself deprived of the load which he expected to secure from the additional factories we all hope to see springing up as a result of the war on German trade initiated by the Government themselves. In point of fact, the co-operation of supply authorities in providing cheap power would reduce the capital required by these factories, for the extra money for the purchase of private plant will have to be found, and it can be safely said that to produce this extra power through the medium of the existing electric supply concerns would in the long run be the most economical course.

The decision is one that will have far-reaching effects, and it would be interesting to hear the views of the industry at large on the subject. One result that it will have immediately is the concentration with greater activity than ever on the sale of energy for valley load purposes, and although the lighting has to bear the bulk of the capital charges, it will have to take care of itself. For one thing, such supplies as are within the restricted outdoor lighting areas will have a breathing space, but those who were hoping to get new plant installed for next winter's load, and have a narrow working margin, will be looking forward to the end of the war with increased eagerness.

There are ample signs that the Treasury policy indicated will be enforced all over the country. Tariffs are already undergoing revision, and other changes also may be necessary, for applications for current under the Acts regulating supply can only be refused on the ground of an extension beyond the stipulated distance, and then only contingent upon the applicant refusing to bear the extra cost, or failing to find satisfactory securities. The question may be raised whether an increased charge should be imposed temporarily to discourage undesirable business, or whether a special clause or order can be obtained to cover the point. The first is a course which, it is to be hoped, may be avoided; the fact that the price of gas has already been raised in several districts on account of the higher price of coal offers an opportunity to demonstrate the stability of electricity supplies, and to command the confidence of the public. Even more desirable is this in the case of charges for power and domestic uses. Increasing the latter especially would tend to cripple and discourage a number of new ventures in cooking and heating appliance manufacture and would lay this promising market open to foreign manufacturers.

We shall watch the development of the policy of the Treasury with concern, for as we have repeatedly stated, the reserve funds available in most electricity undertakings are not all that could be desired. The Finance Committee of the L.C.C. is communicating with the Treasury to obtain a clear understanding as to its views and, meanwhile, the L.C.C. is abstaining from making advances to local authorities and is postponing the completion of any loans which have already been agreed to.

Whatever may be the outcome, the importance of developing to its fullest extent the capital already laid out is very plainly indicated. Every service must be made to produce its greatest possible yield, and every horse-power of plant its largest daily output.

Lead. THERE has been a rather remarkable outburst of strength in the lead market within the past week or so, which took operators completely by surprise, for they did not expect any serious alteration in the main outlines of the position. In the early part of March the supplies coming forward were of quite satisfactory dimensions, and there was some falling off in the volume of business awaiting settlement. There was at the

same time, however, a disposition to realise on the part of holders of speculative parcels, whose attitude was doubtless induced by the poverty of export demands and the almost complete abstention from buying of the home trade. sudden heavy demand, however, sprang up for war supplies, practically the whole of which came from the export markets, notably Russia and France, and this, combined with the difficulty experienced in obtaining deliveries, on account of the congestion at all the ports, where the truculent attitude of the British working man has been deliberately exercised, with the effect of further disorganising trade and checking the successful pursuit of our military and naval operations, forced a very sharp rise in prices. It at once became apparent that dealers were short of lead, and the price was rushed up under the influence of the pressing requirements, which had to be satisfied, more particularly for the earlier available material. There was not so much doing in connection with forward shipments, and the prices of these did not respond to anything like the extent witnessed in connection with earlier shipments, the idea being that considerable supplies of lead are available abroad, notably in the United States and Spain, while output in Australia is increasing. There should, therefore, with any resumption of even very moderate shipping facilities, and with a less impossible attitude on the part of labour concerned with the arrivaland discharging of vessels, be a considerable easing down in the position. It is a disgraceful commentary upon the Trade Union system with which industry is being cursed in this national crisis, that it takes from three to four weeks to discharge vessels arriving here from abroad, even when they contain material necessary for the production of munitions of war. Within the last day or so the more acute phases of scarcity seem to have passed, and there has been a slight relaxation in the stringency, partly arising from the fact that there have been supplies of metal offered from North America. Here again, however, the shipping position militates seriously against the resumption of normal conditions, for sellers in America are unwilling to make sales on c.i.f. terms, as they prefer to throw the onus of shipment on to buyers, who, on their part, regard this as an innovation in the trade, and decline to do business on f.o.b. terms. The broad outlines of the position are: increasing production abroad, huge demands for war purposes, poor general consumption, and a state of affairs in the shipping trade and in labour practically unparalleled in history. When labour recognises the fact that its very existence is at stake, and that by its recalcitrant attitude it is worth a good many army corps to the Kaiser, we shall be nearer the day when prices, not only of metals but of food stuffs also, will reach a level more in accordance with that justified by intrinsic conditions.

LIKE almost every other important The section of the industrial world, the wire-Wire-Drawing drawing trades are at present being taxed Industries. to the utmost to keep pace with the demands from the home markets, as well as from Holland and Sweden in particular. The enormous increase in exports to these two countries of late suggests that these markets, hitherto neglected by this country in the face of the push and enterprise of German firms, are well worth better attention in the future. Unfortunately for the enterprise of the manufacturers of copper wire, &c., in this country, everything at the moment seems to be against the development of these important fields. The tremendous War Office and Admiralty requirements in all copper and bronze productions, the railway and shipping congestion problems, the shortage of skilled labour, and the endless declaration formalities to be gone through before shipment can be made, are questions of such moment that only under the greatest difficulties is a portion of the requirements of these two countries being met, while orders for substantial lines in many cases have perforce to be refused.

The depletion of the ranks of skilled labour, in this as in other trades, has seriously hampered the productive capacity of the important wire manufacturers, &c., throughout the country. It is gratifying to note, however,

that the warnings from the War Office and the Admiralty regarding the necessity for increased production, and the distribution of the war-service badges, have had a salutary effect upon prospective recruits whose skilled labour is so urgently needed for the requirements of the Government.

Lubrication
Troubles.

WHEN a new engine or turbine is first set to work, there is certain to be trouble with bearings in perhaps a majority of

cases. This is because so many constructors neglect the proper cleansing of castings. The writer has seen sent out from an important engine works a main bearing cap of which the oil box was thickly coated with foundry sand more or less adherent to the iron. Castings are never properly cleaned of sand even externally by the still common methods of steel brushing and coke rubbing, and in steam ports and passages it is hopeless to expect cleanliness from such antiquated methods. "Sandblasting" with chilled steel pellets will clean a casting externally, but cannot be relied on for the internal cleansing of ports or oil receptacles. Thus it is that lubrication troubles are so usual when starting up new sets. Of course, modern fashion, there is probably some kind of filtration scheme in the oil cycle, but of what use is this when between the filter and the bearing there is a sandy place of some sort?

Some engineers strongly favour the pickling of castings as the most effective way of removing sand. The castings are first roughly cleaned and fettled, and then hosed with weak hydrochloric acid. Where sand is present this spreads the acid by capillary action, and the result of a few hours of acid action is to remove all sand and leave the iron surfaces clean and free also from the hard siliceous scale which is so destructive of turning tools and other tools, especially millers, and is also most injurious to lathe-bed surfaces and other working surfaces of all machine tools. When the acid treatment has done its work the castings are washed by warm water, and this may be dosed with soda to neutralise any unspent acid. Special attention should be given to all internal parts such as box beds, which act as oil receptacles, as well as to steam and exhaust passages. The oil of any circulating system becomes dirty with use. Dirt comes over from the boilers with the steam and finds its way into turbine bearings in spite of all the constructive care to guard against this. The atmospheric dust gets in somewhere and there may be leakage at oil coolers. There is also the microscopic metallic waste from bearings. All these sources of dirt are quite enough to call for filtration, apart from the gross carelessness which is shown by the presence of foundry sand. Lubrication experts will bear out the truth of the above. Is it not a fact that they are very frequently called on to defend the virtue of the oil they have supplied, owing to the lubrication troubles with newly started plant? Oil may sometimes be at fault if it has been chosen wrongly, but more usually sand, which ought never to have found itself so far from the foundry, is to blame.

Organic oils deteriorate with age owing to their property of absorbing oxygen; this causes them to become gummy or resinous, and thus to lose their lubricating quality. Mineral oils, which are not, chemically speaking, oils, do not absorb oxygen, and are free from this deterioration. It was once partly suspected that even mineral oils underwent some sort of molecular destruction or deterioration, but there appears to be nothing to support this idea, and it can only have arisen from the fact that used oils become thickened and blackened more or less. This discoloration and increase of viscidity is purely mechanical, and can be removed by filtration through proper media such as packed cotton waste. Oil thus filtered is restored to its original purity, and in any circuit of oil usage containing a filter in circuit, the initial oil remains indefinitely, and merely requires to be brought up to the initial volume from time to time, to make good the deficiency due to small losses such as may arise from creep along shafting, small leakages and such wastage as occurs when filtering material is changed.

Enormous quantities of oil are wasted by careless use, and there can be no doubt that much fine machinery is very seriously damaged by the neglect of the very elementary precautions to which attention is drawn above.

# POTENTIOMETER RHEOSTATS. AND RHEOSTATS WITH PROTECTIVE RESISTANCE.

#### BY L. BOOTHMAN.

This article is intended to be supplementary to "Notes on Regulating Resistances" published in the ELECTRICAL REVIEW of February 13th, 1914.

Potentiometer Rheostats.—The "summation watt" capacity of any potentiometer rheostat is given by:—

Maximum field amperes multiplied by excitation voltage, plus the constant watt loss due to the rheostat resistance being across the supply mains.

In the previous article an outline method of figuring the data for a potentiometer was given, but the following has many points of superiority. After the preliminary calculations are made for obtaining the current in field and in rheostat, and curves for these drawn, they can be utilised for other rheostats having a different number of steps, whereas the original method necessitated commencing with a definite fixed number of steps. The calculations are also less involved and any error made is automatically checked.

The following is a practical example and is self-explanatory with reference to the accompanying diagram, fig. 1 (p. 428):—

Excitation voltage v = 440 to 480.

Booster field resistance r = 500 ohms cold, 608 ohms hot. Maximum field current  $c = \pm 96$  ampere.

Total resistance in rheostat R = 2,000 ohms = 8 + P.

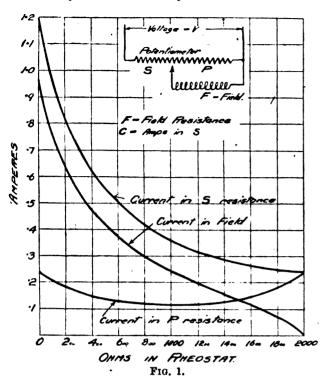

Saries resistance	Parallel resistance P.	11 pg		Combined resistance = B/A.	Total resistance R = B/A + S.	Total amps. c - v/s.	Multiplying factor = P/A.	Current in field = P/A × C.
0	2,000	1,000,000	2,500	400	400	12	.8	.96
20	1,980	990,000	2,480	399	419	1 15	.8	.92
50	1,950	975,000	2,450	398	448	1 07	.796	185
100	1.900	950,000	2.400	396	496	'97	.792	.77
200	1.800	900,000	2,300	391	591	'81	'784	.64
400	1,600	800,000	2,100	381	781	61	'762	47
800	1,200	600,000	1,700	353	1,153	'41	.71	296
1,200	800	400,000	1,300	308	1,508	.32	.62	195
1,600	400	200,000	900	212	1,812	265	'44	1118
1,800	200	100,000	700	143	1,943	'247	'287	.070
1,900	100	50,000	600	83 5	1,983.5	'242	167	.04
1,950	50	25,000	550	45.2	1,995.5	'241	.091	.022
1,970	30	15,000	530	28.4	1,998 4	.24	.036	.013
2,000	0	0	500	0	2,000	.24	0	0

In the first column are arbitrary figures taken for the "s" resistance to give the most suitable points on curves which are shown plotted in fig. 1.

By dividing the total field current ordinate in fig. 1 into the number of steps of the rheostat to be used, the amount of ohmic resistance and current capacity required at each step is obtained. Boosters are usually designed with practically a straight-line load saturation curve over their working range, and the ordinate in fig. 1 can be divided into equal divisions, thus giving equal current (i.e., equal voltage) increments per step. In the case of generators for Ward-Leonard control, by reference to the load saturation curve of the machine, plotted between armature voltage and field current, suitable field current points can be obtained to give equal armature voltage variation per step, i.e., equal speed variation of motor per step.

Rheostats with Shunt Field Protective Resistance.—It is usually required that the protective resistance be so designed that with all rheostat resistance in circuit, i.e., in parallel with same, the field being cold, the minimum field current, that is, minimum voltage is obtained. Also the total ohmic resistance in the rheostat should be so large that the watt loss in the same under these conditions is negligible. Then if the rheostat is cut out of circuit, the protective resistance in series with field will give the minimum voltage on the generator, and this resistance must also be capable of giving rough regulation by means of short-circuiting more or less turns as required. In these circumstances, it therefore will have to

be capable of carrying the actual field current. This point I have found is often ignored by some manufacturers, and the protective resistance is designed for its normal working current only, which considerably reduces the cost.

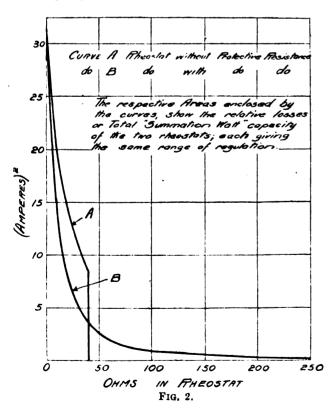

A close approximation to the summation-watt capacity of the regulator rheostat used in parallel with protective resistance is given by:—

1.07 × Rheostat resistance × max. field amps. × min. excitation voltage × protective resistance.

(Rheo. res. × prot. res.) + (rheo. res. × field res.) + (prot. res. × field res.).

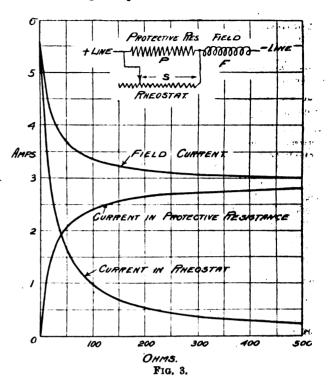

The summation-watt capacity of the protective resistance, to fulfil the above conditions, should equal the summation-watt capacity of an ordinary type field regulator that is

used in the usual manner in series with the field; but under normal working conditions this capacity is not used to the full extent.

In the original patent specification 21,707/05, by Thomas Edge, covering this arrangement of control, a statement

appears that by this method a smaller rheostat can be used, but that is not borne out in practice. This is graphically shown in fig. 2, wherein the relative summation watts for the ordinary type and this type of regulator appear, the respective areas being practically equal; the figure relates to the following example, but is true for others.

A simple method, similar to that given for the potentiometer, to obtain ohmic resistance and current capacity per step of this type of regulator, is as follows:— D.c. generator, 225 volts. Voltage range, 210 to 240.

Field resistance, 39.4 cold, 45.6 ohms hot (F taken as the mean resistance).

Field amperes, c 5.1 max., 2.7 min.

Field protective resistance, P = 210/2.7 - 39.4 = 40 ohms.

Total regulator resistance, s = 1,000 ohms. The various curves are shown plotted in fig. 3.

Regulatorres. in circuit = s.	A = 8 + P.	# × × × × × × × × × × × × × × × × × × ×	Combined resist- ance = B/A.	Total resistance, R = B/A + F.	Field ampered, c = 240/a.	Multiplying factor, v/a.	Current in s = o × P/A	Current in P.
0	40	0	. 0	43	5.6	1'0	5.6	0

100	140	4,000	28.6	71.6	3.36	286	.96	24
200	240	8,000	33 4	76'4	3.12	'167	.23	3.63
300	840	12,000	35.4	78.4	3.02	117	.36	2.71
<b>50</b> 0	540	20,000	37.1	80.1	3.0	.074	.22	28
600	640	24,000	37.6	80.6	2.99	.062	.18	3.81
800	840	32,000	38.2	81.2	2.96	.048	114	3.81
1,000	1,040	40,000	38.2	81.2	2.95	.038	.11	3.81

The voltage taken throughout the range is the maximum of 240, but this is not strictly correct, as with all rheostat resistance "in" the voltage of the generator would be 210.

Electrical Supplies for Neutral Markets.—MESSRS. J. & W. B. SMITH, of London, E.C., have just lately secured a very large contract from the Government of a neutral country for the supply of electrical accessories. Amongst other lines, they are supplying Edison screw lampholders, both 1-in. and batten type, ceiling roses, special D.P. cut-outs with safety plugs, both with and without switches, and 6 and 10-ampere plugs, for heating as well as lighting. We understand that their prices were only slightly higher than the old German prices, and at the conclusion of the war they hope to be able to secure a renewal of the contract, even against German competition.

#### CORRESPONDENCE.

Letters received by us after 5 P.M. ON TUESDAY cannot appear until the following week. Correspondents should forward their communications at the earliest possible moment. No letter can be published unless we have the writer's name and address in our possession.

#### Consulting "Engineers."

With reference to Mr. Stevens's letter of the 2nd inst, question No. 3 he answers himself; I might also add that should there be any doubt as to my statement being correct, perhaps he will try
the experiment of assuming the 10le of a medical man or lawyer.
My aspirations do not necessarily include the degree of B.Sc.;
it would, however, be a desirable qualification for a consulting
engineer to hold.

In my humble opinion, a consulting engineer should not only be a first class mechanical and electrical engineer, but he ought, in addition, to be able to handle matters concerning finance and commerce (so far as they related to his profession) in an expert manner.

Station Engineer.

#### Trouble with Oil.

I thank your correspondents for the trouble they took in answering my inquiry. We have got over the difficulty by closing up the HP. guide apertures altogether, and fitting a small sliding door in front for examination, &c. The set was a new one, and there is another one of the same size a little distance away which has given no trouble. This was simply due to the fact that the draught on the second machine was not strong enough to draw the varour down.

#### Trade with Russia.

With reference to the above matter which you dealt with recently, may I be permitted to add a few remarks, as I have been

With reference to the above matter which you dealt with recently, may I be permitted to add a few remarks, as I have been to Russis on business for a Swiss firm in 1905, a German firm in 1909 and 1911, and for a Franco-American concern in 1912?

I found that there was a good business to be done in practically all electrical apparatus and accessories, but that there were only two methods of doing tusiness: (1) By buying orders among the ordinary Russian agents or dealers; (2) by long credit among the Rusian Jews. The former are the most awkward to deal with, as you have to face the absurd position created by the fact that quality does not count at all, they simply giving the order to whoever pays the most for it. The latter class, however, have the business entirely in their hands in some neighbourhoods. Again, quick delivery and continuous supply of accessories and general stock in the case of agents is a great factor which holds trade in Russia, once the bribery or credit terms have been arranged, as a person will naturally buy a cheap and more or less unreliable article, which goes "off" soon, if he can replace it immediately, rather than a good one which he will get stranded over should it fail. Agents and dealers thus lean towards manufacturers who will keep them up in stock and deliver regularly.

There is, of course, the question of suitable advertisement literature, which is extremely important, but I will leave this in case any of your readers have special questions on this subject.

During all my visits to Russia the Germans were most active and successful in respect to dynamos, motors (A.C. and D.C.), lamps, accessories, general plant, and heavy automobiles. Orders were

and successful in respect to dynamos, motors (A.C. and D.C.), lamps, accessories, general plant, and heavy automobiles. Orders were bought if necessary and almost any long credit terms arranged, while delivery and general treatment were satisfactory; so the "Fatherland" got home.

"Fatherland" got home.

In concluding, I would add that I have yet to come across a Russian who is averse to dealing with British manufacturers, but, on the whole, I found they considered it rather inconvenient and generally impossible. In fact one man told me in St. Petersburg, "It is difficult to know what they sell." I believe, however, that Britishers will stand a very good chance of getting a hold in Russia within two years of the conclusion of peace, but they should be ready to start in full activity right on the ex-German pitch immediately the last-named prospective happy event becomes a reality. If they will not see to it that they get the aforesaid hold, German goods will re-assert themselves, because it is simply "palm-oil" or long credit which are the real assets in Russian business. The country where the goods originate does not matter.

Arthur M. Turner.

London, S.W., March 22nd, 1915.

#### Employment for Disabled Soldiers.

Disabled and partially-disabled men who have become so during the present unfortunate war are already being discharged by the War Office unfit for further service. Such men have pensions according to the extent of their disablement, but in the case of a partially-disabled man it is not sufficient to keep him.

partially-disabled man it is not sufficient to keep him.

There is an excellent opportunity for the makers of electric vehicles to benefit materially, and assist one section of the partially-disabled men, by designing and supplying a vehicle which can be satisfactorily operated by a one-legged man, who in all other respects is medically fit, and would therefore be quite capable of undertaking the driving and control of a battery vehicle, whereas he could not attempt a petrol-driven one.

It merely becomes necessary for the vehicle control to include only one foot pedal, which should be arranged so that it could be operated either by a right or left foot as the case may be. As far operated either by a right or left foot as the case may be. As far as I am aware, most of the battery vehicles have two or more foot pedals. The Edison, for instance, has two large ones and one small one, one of the large pedals being the running and traffic brake, the other one, together with a small auxiliary, being the standstill brake, for which a man requires one foot to press it down and the other foot to lock it. This could be got over by having an ordinary foot model for the summing hards and the standard for the standard for the standard for the standard for the standard for the standard for the standard for the standard for the standard for the standard for the standard for the standard for the standard for the standard for the standard for the standard for the standard for the standard for the standard for the standard for the standard for the standard for the standard for the standard for the standard for the standard for the standard for the standard for the standard for the standard for the standard for the standard for the standard for the standard for the standard for the standard for the standard for the standard for the standard for the standard for the standard for the standard for the standard for the standard for the standard for the standard for the standard for the standard for the standard for the standard for the standard for the standard for the standard for the standard for the standard for the standard for the standard for the standard for the standard for the standard for the standard for the standard for the standard for the standard for the standard for the standard for the standard for the standard for the standard for the standard for the standard for the standard for the standard for the standard for the standard for the standard for the standard for the standard for the standard for the standard for the standard for the standard for the standard for the standard for the standard for the standard for the standard for the standard for the standard for the standard for the standa foot pedal for the running brake and a toothed quadrant hand-brake similar to those used on ordinary chassis. The hand-brake could, if desired, be interlocked with a main switch so that the circuit was broken immediately the hand-brake was applied, and that the hand-brake could not be released until the controller handle had been brought to the "cff" position, but this is a point which is a matter for discussion.

point which is a matter for discussion.

We are about to commence a battery 'bus service in Loughborough, and hope quickly to increase the number of vehicles as the "electric" grows in public favour, and I shall be quite prepared on my part to give such men as I have referred to an opportunity of providing for and supporting themselves if the vehicle makers will do their bit.

Loughborough, March 22nd, 1915.

#### Coke Fuel for Steam Raising.

As the largest makers of special furnaces for burning coke, and

As the largest makers of special furnaces for burning coke, and other fuels, may we be allowed to confirm the recent letter of the expert of the London Coke Committee?

We have for some 30 years fitted several thousands of boilers for burning this fuel at gas works and elsewhere, and during this period we have never heard of any deleterious effects on the boiler plates. Boilers fitted over 25 years ago with our furnaces are still in operation and working efficiently, and we are, or repeat orders and new work, supplying more furnaces than ever before.

It would be interesting to know what the general working conditions were of the boiler on which Mr. H. Boot bases his stricturer. If the life of this particular boiler was short, does he know that it would have been longer if ordinary fuels had been burnt? There may well have been other reasons.

For Meldrums, Ltd. A. BENHAM, London Manager.

Westminster, S.W., March 25th, 1915.

#### INDIAN NOTES.

[From our Special Correspondent.]

Calcutta Port Trust.—At a recent meeting the Calcutta Port Commissioners decided to take all their current from the Calcutta Electric Supply Corporation. This will mean scrapping a seven-year old generating plant at the Kidderpore Docks.

It is estimated that for 1916 the Port Trust will require 3,000,000 units for the Docks and 850,000 units for the riverside berths at Garden Reach. For the years 1917 and 1918 a total of nearly two million units will be required for the latter, and after some few years about 2½ million units annually will be required for the new King George's Dock. When the entire Dock accommodation is finished, in several years the probable total requirements will be not less than 20 million units a year for Docks alone. For the Calcutta Jetties the Commissioners are at present taking about 750,000 units per annum.

This extension means good business for the Calcutta Electric Supply Co. The rate per unit settled upon has not been disclosed; but for quantities such as the above an exceedingly low rate may

be expected.

At present there are murmurings here and there that Calcutta Supply Co.'s rates for lighting and fans, namely, 5½ annas and 3 annas per unit, are too high. The Trades Association have taken the matter up, and put their views before the authorities. It is anticipated, however, that no serious further reduction to the public will be made. One alternative suggested is a flat rate for both fans and lights—this would at any rate save to the consumer the additional capital outlay necessitated by having to wire buildings with two distinct circuits, one for fans and one for lights.

Beductions might also be made in meter rents; and an especially irritating charge, particularly to owners and occupiers in the auburbs, is that for connections from overhead or underground mains to premises—this is often a very large item, totalling up very frequently to a large percentage of the entire cost of the wiring and fittings.

wering and fittings.

"Henley System."—This metal-covered wire system is practically ousting the other systems from the market—namely, teakwood casing and conduit—for wiring installation work. It looks nest, and if well and carefully put up is certainly attractive and not

Time has yet to tell whether it will be as lasting as

the older, if more olumsy, systeme.

Lahore.—The Lahore Electric Supply Co., under the new and enterprising managership of Mr. H. B. Stone, is showing promise of justifying itself. The demand for current for light, fans and factory motors is daily increasing, and large extensions to the generating plant are under way.

#### NEW ELECTRICAL DEVICES, FITTINGS AND PLANT.

#### The "Brilliant" Suction Cleaner.

MESSRS SIMPLEX CONDUITS, LTD., of 116, Charing Cross Road, W.C., have just placed on the market the "Brilliant" electric suction cleaner, which we gather has met with a remarkably good reception.

Special attention has been given to the mechanical and electrical design of the high-speed motor with which the cleaner is fitted, and also to the conformation of the fan blades, which are of cast aluminium. The motor is of the vertical spindle type; bronze alloy bearings are fitted and self-oiling grease cups. The diamond-

FIG. 1 .- "BRILLIANT" ELECTRIC SUCTION CLEANER.

shaped shoe is a patented feature of the machine, and this shoe is over carpets and rugs, and at all times to suck in the air regardless of the thickness of the carpet. The shoe is also fitted with a revolving brush which picks up lint and threads. A series of extra attachments can be supplied and the machine can be adapted as a blower as a blower.

This cleaner, which is described in a leaflet which the Simplex Co. have issued, weighs 8 lb. only, and its price is about the lowest we have heard of for this type of machine.

#### Electro-Medical Apparatus.

In a price list recently issued by the GENERAL ELECTRIC Co., Ltd., 67, Queen Victoria Street, E.C., a variety of apparatus for

FIG. 2.—DENTAL LAMP.

electro-medical uses is described, including induction coils with or without the necessary batteries, apparatus for electrolysis, epilation, &c., and cautery knives. A powerful electromagnet used in the practice of ophthalmic surgeons to withdraw magnetic particles from the eye is listed.

Numerous special kinds of lighting equipment are necessary, one of which we illustrate; this is the smallest dental lamp manufactured, and is claimed to be a great improvement on any other form. It is made entirely of glass, and can be sterilised after each operation.

#### LEGAL.

R. L. JONES & Co., r. ORPHEUM, LTD.

(Concluded from page 353.)

ME. WM. BARBER, A.M.I.E.E., gave evidence in relation to the motor and generators supplied to the defendants. He said that the motor was a good one, but that it was placed in the worst possible place, viz, under the stage, which acted as a sounding box. If he had had the fixing up of the motor he would have placed it outside the auditorium. Even placed as it was, the difficulty as to noise might have been obviated by placing the motor in a case lined with felt, but that would have been carpenters' work, to be done by the employer. He had seen the motor at work at a time when the theatre was empty, but if it had been full he would probably have had to listen to detect the it had been full he would probably have had to listen to detect the sound complained of. He had examined both generators, and had seen one working. He put the load on the machine, and ran it at full load, but it was not sparking badly. In all generators there was bound to be some sparking, but in this case there was not more than the normal sparking of a good generator of the kind running at full load. The machine was in excellent condition, and when it was running the vibration was certainly not such as would injure the building. Had there been any serious vibration it could easily have been cured by placing the motor upon matting which would only have cost a shilling or two. Any generator would be liable to go wrong if it was not in skilled hands; dirt or neglect or not properly adjusting the brushes would tend to the destruction of the machine.

In cross-examination by Mr. Rowan Hamilton, the Witness said it would not be his duty to point out the position in which a machine should be placed unless he were in sole charge of the job. In that case he would suggest where it should be placed, but if he were under the direction of an architect, professional etiquette it had been full he would probably have had to listen to detect the

In that case he would suggest where it should be placed, but if he were under the direction of an architect, professional etiquette would tend to prevent him from making a suggestion. Some gentlemen would be much offended if he spoke to them upon what they would consider an elementary point. The life of a motor-generator ought to be quite a number of years, but whether they got out of order or not depended much upon the manner in which they were worked. A damp situation, such as a new building, would affect the machine prejudicially. He had had cases of burning out in which he could place no blame upon anyone,

MR. ROWAN HAMILTON: I am glad to hear you say that.

MR. WALTER HENRY JARVIS, electrical engineer in the employ of Mesars. Baxter & Gaunter. Ltd., of 219. Tottenham Court Road.

MR. WALTER HENRY JARVIS, electrical engineer in the employ of Messrs. Baxter & Caunter, Ltd., of 219, Tottenham Court Road, said that his firm were electrical contractors for Admiralty work, for the Metropolitan Asylums Board, for the London County Council, and for other bodies, and they were sole London agents for Newtons, Ltd., manufacturers of motor-generators. He visited the Orpheum Thestre, at Croydon, on the previous Mondey and inspected the two generators. In one he found that the solder had been melted, and a wire detached, which caused an open circuit, and led to a good deal of sparking. The condition in which he found the generator was due to overloading. He repaired the machine and ran it for about a quarter of an hour at full pressure and during that time no defect was disclosed. The only way in which he could account for the defects which he found was that which he could account for the defects which he found was that there had been overloading. He saw the machine again on the following Saturday, when it was running at full load quite

satisfactorily.

MB. ROWAN HAMILTON, in opening the case for the defence. admitted that the defendant would have to pay a certain amount towards the generators, but contended that owing to the way in which they broke down, and the unsatisfactory way in which they did their work, they were entitled to a reduction in the price. With regard to the motor, he said his case was that it was quite useless, and had not been used since it was first put in and tried.

In support of his statement Counsel called evidence to show that

neither the motor nor the generators were satisfactory, and that the former made a great deal of noise when working.

ME. VEREY, the Referee, in giving judgment on Tuesday, March 16th, said that counsel for the defence had taken every point which he could possibly have taken, but had failed to satisfy him. It was an admitted fact that after the motor and generators were It was an admitted fact that after the motor and generators were delivered some little repairs were required, but when those repairs had been done the generators ran from May to November without any complaint being made. Then when the solicitor wrote for money the defendants put in a plea of noise and damage to the building. It was for the defendants, when they refused to pay, to show that the machines were defective; but after considering the evidence he came to the conclusion that they had failed to prove that the generators were defective, or that there had been any breach of contract. The plaintiffs were, therefore, entitled to recover the full amount which they claimed in respect of the generators—£96 11s. 10d. The motor rested on a different footing. The defendants were entitled by the contract to have a motor pro-

perly made and of good materials, but they said that supplied was too noisy. When the theatre was designed no place was provided for a motor, as at that time it was not intended to have a motor to raise the curtain. The defendants afterwards changed their minds and ordered a motor, and by direction of Mr. Booth, the architect it was not a good place. architect, it was put under the stage. That was not a good place, and several suggestions were made as to a means of keeping out the noise. The plaintiffs, however, were not allowed to do anything, and he considered that they had not been guilty of any breach of contract, and they were entitled to the full amount claimed. Judgment would, therefore, be for £136 11s. 10d., the solaimed. Judgment would, therefore, be for £136 11s. 10d., the £96 11s. 10d. paid into Court under Order 14 to be paid out in part satisfaction of the judgment.

Judgment was entered accordingly, with costs.

#### WITHHOLDING E.T.U. FUNDS.

AT the Salford Police Court recently, E. S. M. Karslake, electrician, of Southampton, was summoned by the Electrical Trades Union for withholding £18 10s. 11d., the moneys of the Union. It was stated at the outset that the Southampton police had served a summons on the defendant, and the latter had written to the Salford Chief Constable, stating that he was willing to attend Court, but that he had no means to get there. It was decided to

go on with the case

go on with the case.

MR. REED, for the Union, said the prosecution was taken under Sec. 12 of the Trade Union Act of 1871. Defendant was the branch treasurer of the Union at Southampton, and the Union's registered office was at 137, Great Clowes Street, Broughton. The prosecutors did not ask for a penalty, but simply wanted to recover their moneys. On December 15th, 1913. which was about the time the moneys should have been paid over to Mr. Rowan (the secretary of the Union), a telegram was received from the defendant in the following terms:—"Robbery, E.T.U. money. Police informed." Following a meeting of the Committee of the Union of his telegram, and on December 27th defendant wrote a letter. his telegram, and on December 27th defendant wrote a letter, stating that he had been called home from his work to find that the house had been broken into. The Union communicated with the Southampton police, and inquiries had been made. An examination of the premises revealed no signs of any breaking in, and the police, said Mr. Reed, did not believe defendant's story. Application was subsequently made to defendant to pay the money—whether stolen or not defendant was responsible for the safe custody of it—but without success, and a summons was issued on Roberton 28th. February 28th. There was an enormous pressure at all Government dockyards and at other places, and there was no resson why an order should not be made for the payment of this money by defendant. It was a serious case for a Trades Union with branches all over the country if their moneys were to be withheld in this

The CHAIBMAN (Sir Wm. Stephens) said the prosecutors seemed to have been extraordinarily patient with this man. The Bench had decided to make an order for defendant to pay £18 10s, 11d., and 20s. costs, or in default six weeks' imprisonment, the committal not to issue for 14 days.

#### WORKMEN'S COMPENSATION.

At the Ashton-under-Lyne County Court, on March 18th, sanction was given to a settlement of a case between Robert Dodd, a packer, of 30, Brook Street, and the Tudor Accumulator Co., Ltd., Dukinfield. It was stated that Dodd had contracted lead poisoning, and, although the firm disputed liability because the man had not been doing any work in connection with lead for 12 months, they had agreed to pay £75 and an agreed sum for costs in settlement. For the applicant it was stated that the terms were satisfactory, and Judge Brown gave his sanction.

CONSOLIDATED LANGLAAGTE MINES, LTD., v. VICTOBIA FALLS AND TRANSVAAL POWER CO.

AT the Bloemfontein Appeal Court the appeal in this case was recently heard. In the lower Court plaintiffs were awarded £36,269, less the present value of £25,750 recoverable at the close of the life of the mine, which was fixed by consent at 22 years, the amount awarded thus being £29,328 with interest. The Appeal Court, by a majority, has arrived at the decision that judgment should be given for the plaintiffs for £19,000 and costs, but the costs of the appeal are to be borne by the plaintiffs. The case was a claim for damages sustained by the plaintiffs by reason of the failure of the defendants to supply in terms of an agreement additional power required.

BRITISH INSULATED AND HELSBY CABLES, LTD., v. CRITTALL MANUFACTURING Co., LTD.

On Monday last, Mr. Muir Mackenzie, in this case, gave judgment for the defendants, with costs of the action. Judgment on the counterclaim was entered for the plaintiffs, with costs of the counterclaim. We shall report the judgment in our next issue.

HAMILTON r. MARCONI'S WIRELESS TELEGRAPH CO., LTD. AFFER 15 days' proceedings, the hearing of this case was concluded on Tuesday. His LOBDSHIP proceeded to sum up, but the Court adjourned before he had finished.

#### WAR ITEMS.

Feeling in the U.S.A.—The following interesting extracts are from a Sydney University Engineering Graduate now in the service of the General Electric Co. in America—Mr. J. P. Tivey, B.A., B.E. We quote from the Sydney Morning Herald, B.A., B.E. V January 23rd :-

"Once and for all let me tell you that if popular opinion in America had its way to-day, then America would be fighting side by side with England. I have just been for two months travelling by side with England. I have just been for two months travelling over the United States, and speak from my own personal knowledge of the intense and bitter anti-German feeling. This is true even in St. Louis, which is perhaps the largest German settlement in America. So bitter is the whole of the American Press that the German Ambassador has protested several times to the President. I may say that the English cruisers on patrol duty in the Atlantic were supplied from New York. And the authorities winked at it until the German Ambassador again protested at the breach of neutrality. If you have any chance, you should fistly winked at it until the German Ambassador again protested at the breach of neutrality. If you have any chance, you should fatly deny as a foul calumny any statement that America is not entirely sympathetic with the Allies. I am in no 'half-friendly' country, but in the midst of very warm friends of our country and cause. Your remarks about South America are quite wide of the point. The greatest trade with that country by far is held by England. The greatest trade with that country by far is held by England, whose financial interests there are so great that South America is little more than an English dependency, and America knows it. They are seeking to take the German trade with that country, but They are seaking to take the German trade with that country, but frankly realise that they cannot take England's, nor do they appear anxious to try. Yes, the President is a pacificist, and a good thing for Germany, or that perjured country would have another foe to fight. I feel very strongly on this point. Some foul liar or German sympathiser is trying in Australia to impeach America. Deny it, just as you would deny the most hideous lie ever told. You have heard the song 'It's a Long Way to Tipperary.' That song is sung nightly in practically every theatre and picture show in the U.S.A., and is usually encored three or four times."

The Trade Position in Canada.—The following has been received at the Commercial Intelligence Branch of the Board of Trade from the office of His Majesty's Trade Commissioner for Canada, under date February 25th:—"The financial situation has improved to some extent and has brought about a general improvement aways to have been approximately as the proportion of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the comment of the ment in business. Although this improvement emanates primarily from the rural centres, the influence of war orders on industry is also apparent. It is somewhat difficult to generalise with regard to collections, but from all reports and opinions available, although the improvement so far noted seems small, the consensus of opinion is that in the next few months collections will improve, owing to the growing prosperity of the agricultural community. Commercial failures for January have been heavy, which would point to the fact that a great many of the smaller firms who were existing on speculative lines are being ousted from the market.

... The wholessle hardware trade appears to be picking up gradually, and should soon be on a normal basis; a pronounced activity in lines of this nature is expected to be felt towards the beginning of next month (March). Many business men are of the opinion that there will be considerable activity in the building trade throughout the Dominion in the coming spring. Generally speaking, the situation in the markets of the Dominion is improving, and British manufacturers who are desirous of retaining their hold, as well as those who are desirous of introducing their manufactures, should take advantage of the present position in order to become firmly established, so that when commercial activity generally assumes a more normal basis they will be strongly fortified and well able to meet their competitors." is that in the next few months collections will improve, owing fortified and well able to meet their competitors."

Allowances to Dependents.—In a report just issued the Tynemouth Electricity Committee draws attention to a decision of the Council, arrived at in September last, whereby a gratuity, payable weekly, was granted to the dependents of the two naval reserve men who left the works to join one of the three cruisers which were torpedeed in the North Sea. In this connection the which were torpedoed in the North Ses. In this connection the electrical engineer reports that the widow of one of the men is earning her own living, but that the widow of the other would be unable to do so for some time to come. The Committee has decided to terminate the present arrangement as regards the former case, on the expiration of three months from the present time, and to continue the arrangement for a further period of 12 months as meaning the widow of the other late employ. The 12 months, as regards the widow of the other late employé. electrical engineer has experienced difficulty in securing men for the switchboard and in the mains department. In this connection the Committee has adopted the recommendation of the engineer as to the appointment of a man for the switchboard, and has decided to give the chairman plenary powers to fill up the vacancies in the mains department.

Russian Mica and Wolfram.—A Petrograd paper says that the Russian electrotechnical industry, so largely dependent on Germany, has suffered also from the want of mica, which used to be imported from that country. Now, however, successful experiments are being made in Moscow in the handling of mics, of which large deposits exist in Siberia and of finer quality than that hitherto imported from Germany. A Petrograd paper say that wolfram is being produced in Transbaikalia along with mica.

Magazines for the Forces.—We have received a copy of the second number (April) of Khaki, the monthly magazine with cabled news sheet. It appears to be still more interesting, both in its literary features and its illustrations, than the March issue. The publishers have decided to extend their policy so that the paper may be sent free, not only to Overseas soldiers, but to the British Army and Navv.

A Melbourne Electrical Contract.—According to the Sydney Morning Herald the Melbourne City Council at a meeting held early in February had before it a request from Messrs. Siemens Bros. Dynamo Works, Ltd., asking it to reconsider its decision, "That tenders be invited for the 5,000 kw. plant, excluding plants of Austrian or German manufacture or capital," with a view to excluding the company from the operation of that resolution. The company's general manager for Australasia also wrote stating that if such action were to be universally adorted it would cause that if such action were to be universally adopted it would cannot the company to be shut down, entailing great hardship upon a large number of British employés and their dependents. The Council decided merely to receive the letter, but "no definite policy is laid down for the future."

Germans and Australian Trade.-According to the Sydney newspapers, German firms are continuing to try to do business with Australian importers through Swiss, American and Italian agents. The letters are written at German factories and give addresses of such agents to whom orders may be addressed. Such communications have been under consideration at the Perth Chamber of Commerce meeting, and the President said that the Germans who sent them out evidently took the addressees for a pack of fools. "They were asking British merchants to supply them with the money necessary to build more battleships and Zeppelins, for the purpose, to put it bluntly, of murdering their relations and friends."

The Sydney correspondent of the Times, quoting an Australian newspaper article, says that Germans in Australia scoff at the idea of a post bellum boycott. "They frankly declare that their troops, before an evacuation of the occupied territory, whether forced or by treaty, will destroy all factories and machinery and all means of manufacturing commodities in Northern France and Belgium. Thus, at the end of the war, the world will be compelled to purchase in Germany stuffs and other goods which were formerly the produce of the devastated districts."

Hospital Lighting.—Mr. E. M. Ashley has given the electric lighting installation for the St. John Voluntary Aid Detachment Hospital, Roe Lane, Southport.

Personal.—The supplement to the London Gazette for March 17th contains the information that Second Lieut. H. Clifford 17th contains the information that Second Lieux. H. Unnoru Palmer (manager of the G.E.C. Publications Dept) has been appointed captain (temporary) in the London Scottish, other-wise known as the 14th (County of London) London Regiment. The appointment dates from March 4th. Captain Palmer has recovered from the effects of his recent operation.

In the London Gazette the following appears:

Territorial Force.—London Electrical Engineers.
Geo. Ernest Owles to be Second Lieutenant. March 20th.
Christopher Levett to be Second Lieutenant. March 20th.

Lieut. Harry Byng, third son of the late Mr. Gustav Byng, who our readers will remember as the founder and late chairman of the Gemeral Electric Co., Ltd., was married very quietly on Monday, March 22nd, at St. Mary's, Bryanston Square, to Miss Evelyn Curtis, of Boston, U.S.A. Lieut. Byng, who is in the Border Regiment, had only just returned from the front on five days' leave, and is now on his way to the front again.

Roll of Honour.—The Times states that Rifleman Basil Heath-cote Clarke, Queen Victoria's Rifles, who was killed in action in France on March 6th, was a member of the office staff of the London Electric Supply Corporation, Ltd.

Private Seth Bond, an electrician at Fleetwood Electricity Works, has died in Northern France from a wound in the head caused by a hand grenade. He volunteered for service with the 5th King's Own Royal Lancaster Regiment, at the outbreak of the war, and had been at the Front five weeks.

#### BUSINESS NOTES.

Galvanising.—Electro-galvanising is now an industry of considerable importance; every shippard of importance and every dockyard throughout the world has an electrogalvanising plant for the coating of boiler tubes, and the process is also largely used for coating iron and steel when it is important that the tensile strength should not be affected, and for machined and finished work which has threads or sorews cut upon it, or accourately fitting parts, as these are not filled up, as is the case if they are coated with zinc by the hot process: the coating of zinc is also evenly distributed. Mr. Cowper-Coles, who erected the first plant at Messrs, Cammell Laird's yard at Birkenhead in 1893, informs us that he has recently made important improvements in the process received in the section of small ments in the process, especially in regard to the coating of small articles—such as bolts, nuts and tubes—and has erected a plant for this purpose at Sunbury-on-Thames.

**Book Notices.**—Port of Hull Annual, 1915. Hull: H. E. C. Newbam. 1s. net.—This is a 70-page, fully illustrated publication, wherein the editor and publisher has endeavoured to bring together, for the information of allied nations, particulars of the magnitude of the facilities, and the extent and variety of the manufactures produced in "this quarter of England." The letter-press is partly given in both the English and French languages, and deals with such matters as the immense dock facilities of Hull, statistics of shipping trade, list of Hull-owned steamships, coal trade in 1914, grain trade, imports and exports, and so forth.

Tables Annuelles de Constantes et Données Numériques. Vol. III, Aunée, 1912. London: J. & A. Churchill. Price 28s. 6d. net.— This volume contains the record of constants and data published in 1912 in connection with all branches of chemistry, physics and technology, under the supervision of an international Committee of distinguished scientists, assisted by national Committees, and supported with subventions by all the principal Governments, as well as by numerous scientific societies, companies and individuals. In the present issue of this monumental work the facilities for reference have been improved by the addition of an alphabetical index to the substances dealt with, other than chemical compounds. While it is not practicable to give a complete index in each volume, the International Committee purposes publishing one for the whole of the first five volumes when these have been isened.

Regarding the contents of the body of the work it is impossible to enter into detail; we are confronted with an enormous mass of the results of research, covering the whole universe. From the alphabetical table we take the names of Coals, Concrete, Galalith, Graphite, Gutta-Percha, Insulating Materials, Paper, Porcelain, Graphite, Gutta-Percha, Insulating Materials, Paper, Porcelain, Rubber, and Steel, as representing subjects of interest to many of our readers. As an example of the contents, the section "Conductivity of Electrolytes" extends over 19 pages, and "Electromotive Forces" over 23. The labour involved in preparing the copy, in the very difficult type-setting, and in the arduous proof-reading, must have been enormous. We could wish that a further improvement might be made—that the chief table of contents should be arranged in some sort of alphabetical order instead of order of position; this would not require any greater space, although the items are given in four languages, and would obviate a good deal of inconvenience.

Commencing with this issue, an important departure has been

a good dear or inconvenience.

Commencing with this issue, an important departure has been made; in order to facilitate the use of the data by specialised trades, &c., it has been decided to issue some of the sections separately, each forming a bound volume complete in itself. We have received three such sections relating to electrical matters, and these will be reviewed more fully in later issues.

these will be reviewed more fully in later issues.

Business Prospects in India. By A. T. Stewart. London: Francis Hodgson. 2s. net.—We briefly referred to the author's Russian pamphlet in our last issue. The present one is a companion, in the same series, which will appear in the course of a few days. A good deal of information is given respecting various classes of imports, concerning Germany's growing control over exports of India's raw material, and showing the Indian imports from Germany and Great Britain comparatively. The author holds that just now, when British prestige is so high with the people of India, we should proceed to overhaul and reconstruct our trading system with the country. The methods adopted by German traders in their efforts to oust us commercially from India are reviewed, and it is suggested that we must not be afraid to take a leaf out of our rivals' books. For the electrical trade, co-operation between a number of English firms in a conjoint attack is recommended.

The second issue of the Electric Vehicle—the official organ of

a number of English firms in a conjoint attack is recommended.

The second issue of the Electric Vehicle—the official organ of the Electric Vehicle Committee—has just appeared, and copies can be obtained from the publishers, at 13, Fisher Street, Southampton Row, W.C.; the Committee hopes that central station managers will distribute them amongst users of all kinds of vehicles in their respective districts. The number contains many interesting items, not least of which is a list of "electrics" in use and on order in Great Britain, which now extends to a total of 483; in December it was 100, but only part of the increase represents new items, the remainder being apparently due to information received since the first list was compiled. None the less, it is an impressive total, and full of promise for the future. We note that in the United States the total is no less than 75,000. An interesting item is an illustrated description of a wayside boosting device, provided by Mr. A. C. Cramb at Oroydon for a special service of electrical vehicles.

of electrical vehicles.

"First Principles of Production." By J. Taylor Peddie. London:
Longmans, Green & Co. Price 5s. net.

"Bulletin de la Société Internationale des Electriciens." Vol. V,
No. 39, February, 1915. Paris: Gauthier-Villars. Price 3 fr.

"The Mathematical Analysis of Electrical and Optical Wave
Motion." By H. Bateman, London: Cambridge University Press. Price 7s. 6d. net.

"The War and the Parting of the Ways." By C H Luke. London: Sampson Low, Marston & Co., Ltd. Price 1s. net.

For Sale.—The Receiver for debenture-holders of the British Prometheus Co., Ltd. (in voluntary liquidation), invites offers for the purchase of the business as a going concern. Newport Corporation has for disposal 18 tons of old lead battery plates. Particulars are given in our advertisement pages to-day.

Catalogues and Lists.—Messrs. Siemens Bros. and Co., Ltd., Woolwich.—16 page pamphlet (No. T 535) containing a fully illustrated description of their "Autophone" system—an automatic telephone system for large business houses, factories and institutions.

MESSRS. LANDIS & GYR, Elgee Works, Stonebridge Park, Willesden, N.W.—Leaflet describing their prepayment meters—ampere-hour meters for D.C. circuits, and watt-hour for single-phase circuite

GILBERT ARC LAMP Co., LTD., Sphere Works, St. Albans.— Four-page illustrated price list of fittings for half-watt nitrogen filled and metal-filament lamps. Various types for street, railway, works and shop lighting are shown

THE GENERAL ELECTRIC Co., LTD., 67, Queen Victoria Street London, E.O.—24-page catalogue (O section, ninth edition) of electro-medical apparatus, novelties, &c., including apparatus for electro-therapeutics, battery lighting sets, battery fans, cells, galvano-cautery apparatus, measuring instruments, medical lamps, vibro massage, &c. All articles are well illustrated and prices are

vibro massage, &c. All articles are well illustrated and prices are clearly shown.

CITROEN GEAR Co., LTD., 27, Queen Victoria Street, London, E.C.—One of the best prepared catalogue publications that we have received since the war began. Sixty-eight pages of thick art paper are filled with excellently produced and printed half-tone pictures of mining, pumping, electrical, rolling mill, marine, and textile machinery, machine tools, rubber machinery, compressors, turbines, electric traction, equipment and motor-cars, on which the Citroën gears are used. The letterpress discusses all of these applications briefly, and gives an account of the evolution and advantages of the gears, together with an account of how they are cut, and of the works in which they are made.

THE CABLE ACCESSORIES, LTD., Britannia Works, Tividale, Tipton.—Bound catalogue of 112 pages, containing illustrations and prices of a host of different types and designs of "Revo" watertight electric light fitting. They are designed for metal filament and half-watt lamps, and for all kinds of situations—mills, shop windows, street lighting, ships, and so forth. Single light fittings, cluster designs, cargo lights, bulkhead lights, bracket arms, hand lamps, replacement fuses for street lighting fittings, and other manufactures, are included in what should be a very useful catalogue.

Messes A. P. Lundberg & Sons 477 to 489. Livetpool Road. catalogue.

MESSES. A. P. LUNDBERG & Sons. 477 to 489, Liverpool Boad, messes. A. P. LUNDBERG & SONS. 477 to 483, hiverpool Road, London, N.—List (S 28) is the firm's revised and enlarged "Mar-vel" switch list (12 pages). Various standard uses and methods of connection of "Marvel" and "Marvel intermediate" switches are detailed, and a number of modifications are diagrammatically shown. Prices of surface, flush, and pendant patterns are

MESSES. MILLES ELECTRICAL Co., 87 and 38, Strand, London, W.C.—Pamphlet giving tabulated prices and particulars, and a specification, of M.E.C. interpole dynamos and motors, from ‡ to 76 B.H.P. Copies of the pamphlet will be sent on application. The business has been started by Mr. Percy M. Millns, who until

racently was chief sales engineer in the machinery department of the Adnil Electric Co., Ltd.

MESSES. W. T. GLOVER & CO., LTD., Trafford Park, Mauchester.

An illustrated pamphlet, entitled "Hints on Electric Cables for Collieries," written by Mr. W. T. Auderson, giving the reasons which have led the firm to advocate the use of vulcanised bitumen

cables for mining work.

BRITISH THOMSON-HOUSTON Co., LTD.. Rugby.—Illustrated price-list No. 2,155 gives particulars of B.T.H. A.C. loom motors—squirrel-cage, three-phase, 50 cycles.

British Engineering in China.—Eastern Engineering British Engineering in China.—Eastern Engineering states that a very powerful and well-organised corporation, comprising some of the best known engineering firms in Great Britain, has lately come into existence for the purpose of co-operative working throughout the Chinese Republic. Such firms as Sir William Arrol & Co., Ltd.; Brooks & Doxey, Ltd.; John Brown & Co., Ltd.; Cravens, Ltd.; Callender's Cable and Construction Co., Ltd.; Cravens, Ltd.; Callender's Cable and Construction Co., Ltd.; Dorman, Long & Co., Ltd.; Thos. Firth and Sons, Ltd.; B. and W. Hawthorn, Leelie & Co., Ltd.; Hulse and Co., Ltd.; W. S. Laycook, Ltd.; Simon Carves Coke Oven Co., Ltd. together with a number of other manufacturers having complementary interests, have, after a careful study of the conditions of together with a number of other manufacturers having complementary interests, have, after a careful study of the conditions of trading now ruling in China, joined forces to form a company, which, registered in London under the title of "Representation for British Manufacturers, Ltd.," has, during the past year, established a joint account organisation for covering the important centres of the Chinese Republic, with head offices in London and Peking, and branches at Shanghai, Hankow, and Canton.

Prices Advance.—MESSRS. VERITYS, LTD., announce that from March 1st their electric light fixture list, Vol. III, second edition, is subject to an advance of 10 per cent.

Firé.—On Tuesday night a serious fire occurred at the works of MESSES. ALLDAYS & ONIONS, at Birmingham.

Social.—The annual supper of the employes in the meter department of Messrs. Ferranti, Ltd., Failsworth, took place at the Star Inn a few days ago, about 50 persons attending. J. C. Leadbeater presided.

-The three men who were charged Alleged Stealing.with being concerned in the theft of X-ray apparatus from London hospitals, as mentioned in our issue of March 12th, were, on 19th inst. committed for trial.

-THE CENTRAL WIRELESS Co., LTD.-Liquidations.-A meeting of creditors was held on Monday last at 45, Newhall Street, Birmingham. Liquidator, Mr. R. B. Earle.

Street, Birmingham. Liquidator, Mr. R. B. Earle.

CONSOLIDATED DIESEL ENGINE MANUFACTURERS, LTD.—We have received a summary of the accounts of the liquidator (Mr. Wm. B. Peat) from July 7th. 1914 to January 6th, 1915. The receipts have amounted to £12,482, less payments to execution and other secured creditors £208, and payments per trading account £2,656, leaving £9,618. On the payments side there are Board of Trade and other fees, law costs of petition, liquidator's fees, and salaries, wages and other charges, after the deduction of which, together with £157 in respect of preferential creditors, there remains a balance of £8,155. there remains a balance of £8,155.

ROUNDHAY AND DISTRICT ELECTRIC LIGHTING CO., LTD.—A meeting will be held on May 4th, at 34, Albion Street, Leeds, to hear an account of the winding up from the liquidator, Mr. W. Smith.

Bankruptcy Proceedings.—J. P. K. CLARK (G. Driver and Son), electrical and mechanical engineers, Hythe Road. Willesden, N.W. Adjudication order March 16th.

Trade Announcements.—Messes. Pyne, Hughman ND Co., have removed from Lyons Range to Grosvenor House, Old Court House Street, Calcutta.

MESSES. E. BROOK, LTD., announce that their London office was yesterday removed to 11, Queen Victoria Street, London, E.C. Telephone No.: City 4468. The premises are central and commodicus, and will enable a larger stock of single; two and three-phase motions to the committee of the committee of the committee of the committee of the committee of the committee of the committee of the committee of the committee of the committee of the committee of the committee of the committee of the committee of the committee of the committee of the committee of the committee of the committee of the committee of the committee of the committee of the committee of the committee of the committee of the committee of the committee of the committee of the committee of the committee of the committee of the committee of the committee of the committee of the committee of the committee of the committee of the committee of the committee of the committee of the committee of the committee of the committee of the committee of the committee of the committee of the committee of the committee of the committee of the committee of the committee of the committee of the committee of the committee of the committee of the committee of the committee of the committee of the committee of the committee of the committee of the committee of the committee of the committee of the committee of the committee of the committee of the committee of the committee of the committee of the committee of the committee of the committee of the committee of the committee of the committee of the committee of the committee of the committee of the committee of the committee of the committee of the committee of the committee of the committee of the committee of the committee of the committee of the committee of the committee of the committee of the committee of the committee of the committee of the committee of the committee of the committee of the committee of the committee of the committee of the committee of the committee of the committee of the committee of the committee o phase motors to be carried than was formerly the case

THE METAL INFORMATION BUREAU (L. H. Quin) has removed to larger premises at 7, East India Avenue, London, E.C. Telephone No.: Avenue 3835. Telegrams: "Quinirage, Led, London."

THE A. & A. ELECTBICAL Co., LTD., has removed to 51, Whitcomb Street, Leicester Square, London.

## LIGHTING and POWER NOTES.

Aldershot.—Proposed Loan.—The U.D.C. has decided to expend £8,350 on the provision of additional generating plant, &c., at the electricity works, and to apply for a loan of £8,500. With reference to a suggested supply of current to the parish of Hale, the clerk has advised that an order will be necessary, together with the consent of the Farnham E.L. Co., who have power to supply. Further inquiries are to be made into the matter.

Australia. — The Romsey Shire Council has been authorised to supply electric light to Lancefield.

The Brunswick Municipal Council has decided to borrow £10,000

for electricity purposes.

The annual report of the Melbourne Electricity Supply Committee shows gross receipts amounting to £164,000, an increase of 9'6 per cent. over last year, and a gross profit of £84,796, or 11 per cent. increase, the net profit being £21,051.

Barnet.—Workhouse Lighting.—The Guardians have decided not to invite tenders at the present time for the supply of electrical plant for lighting and heating the whole of the institution, but to ask the North Metropolitan Electric Power Distribution Co. to supply a draft agreement for lighting and heating during a period of seven years, at 1d. per unit, plus a yearly sum of £50. An electric lift is to be installed at the new Infirmary at a cost of £250.

Basingstoke.—Power Supply, &c.—The Corporation Basingstoke.—Power Supply, &c.—The Corporation has received an application from Messrs. Thornycroft & Co. to supply their vehicle and engine works with electric power to the extent of a minimum of 250,000 units per annum, at 1½d. per unit, for four years certain, subject to a formal agreement and to the consent of the L.G.B. to the necessary loan to carry out the work. Earl Curson, of Hackwood House, and Mr. L. de L. Simonds, of Audley's Wood, are to take a large supply of current for lighting

Bedford.—Additions and renewals of cables are to be carried out by the Town Council, at a cost of £715. The electrical engineer has been instructed to construct a sub-station in Campbell

Blackrock (Co. Dublin).—Proposed Loan.—The L.G.B. has intimated to the Council that, before considering the proposal to borrow £13,000 for an electric lighting scheme, it would require complete plans and specifications; these have now been supplied.

Bootle.—YEAR'S WORKING.—The electricity surplus for the current year will amount to about £3,017, or £1,061 more than estimated; the income from sales increased 9 per cent., while working cost remained almost stationary. It is preposed to transfer £1,500 to the rates account, and the balance to the reserve fund. The estimated surplus for the next financial year is only £1,142, owing to increased charges due to the war amounting to £2.694.

Bradford.—WAR BONUSES.—The City Council has decided to grant war bonuses to all employés for a period of six months from March 1st, in amounts varying from 1s. to 3s. per week, which will involve a cost of £15,000.

Brighton.—INCREASED PRICES.—In consequence of the increased cost of coal, &c., the T.C. has increased the various flat rates for private lighting by \( \frac{1}{2}d. \) per unit; the maximum demand rate from 6d. and 2d. to 6d. and 3d.; the rate for public lighting by \( \frac{1}{2}d. \) per unit; and the power rate from 1d. to 1'10d. per unit, discounts being abolished.

The T.C. has decided to renew the condenser tubes of No. 2 tur-

bine set, at a cost of £590.

Burnley.—YEAR'S WORKING.—The electricity profits were £5,200, compared with an estimate of £5,970. An increase in the price of electricity was approved. The surplus on the tramway undertaking for the past year was £3,500.

Bury.—The Electricity Committee has decided not to proceed with the extension at the Chamber Hall power station at

Cardiff.—FLY-WHEEL WRECK.—The power station at Cardiff was severely damaged on Sunday last by the bursting of a fly-wheel, weighing 70 tons, which wrecked an engine, and led to the complete suspension of the tramway service. The damage is estimated at £20,000.

At an emergency meeting of the Tramways and E.L. Committee At an emergency meeting of the Tramways and R.L. Committee, Mr. Arthur Ellis, the city electrical engineer, said one large engine had been entirely wrecked, and, in his opinion, it would pay to replace it with modern plant, rather than repair it. He had no doubt that the engine speed suddenly increased, and the bursting doubt that the engine speed suddenly increased, and the bursting of the fly-wheel and generator followed, shattering the end wall and most of the roof. It was necessary to give temporary cover to the remaining plant, but the greatest difficulty was the 20-in circulating water pipes, which had been broken, flooding the basement and damaging the foundations. As soon as the concrete was removed the waterworks department were prepared to erect new pipes, so that the new plant could be run. The large battery at the Hayes station had kept going the lighting of the city and most of the public buildings, until the old generating plant could be started. He hoped that they would have the lighting service restored fully by Tuesday (last) and be able to start a restricted service of care. It appeared that the engine had only been on load five or 10 minutes, when the driver noticing something wrong, had barely 10 minutes, when the driver noticing something wrong, had barely time to warn the staff to get clear. An observer outside the station said he saw a huge volume of black smoke shoot upwards followed by a number of projectiles, and immediately after the power station was hidden in a cloud of steam.

Chislehurst.—The U.D.C. has been informed by the Chislehurst Electric Supply Co. that there is no prospect of a redution in the price of current in the near future, owing to the unremunerative lengths of main laid, and that the widely scattered area did not allow of any fair return on the capital expended.

Continental Notes .--Norway.-It is reported from Skein that the Hollen municipality has decided to expropriate the Eidsfos waterfall.

According to a report from Stavanger the work of harnessing the large waterfalls at Saude was to be started last month.

At Enebak to the north of Kristiania a new municipal electrical

station, with a capacity of 1,900 H.P., has been completed.

SPAIN.—A concession has been granted for the establishment of a plant to utilise the water power of the River Rambla de Almohoga at Almohoga (province of Teruel) in the generation of electrical energy for power purpose

RUSSIA.—ELECTRIC POWER IN OIL FIELDS.—The output of electricity in the Baku oil field increased from 20,000,000 kw.-hours in 1906 to 53,000,000 kw.-hours in 1912.—Financier.

Faversham.—The T.C. has adopted a recommendation from the Electric Supply Committee not to increase the cost of

Galashiels.—The Galashiels and District Electric Supply Co. has now commenced supplying oustomers. Two mills are taking all the power for their plant, and a third is having the necessary equipment installed; other consumers for power and light have been connected up. The company's works are situated at Galafoot, and the plant installed has a capacity of over 2,000 H.P.

Glasgow. - The Markets Committee has decided to retain the present are lighting in the markets and to light the extension of the fish market by electricity.

Gresford .- Proposed E.L. Scheme. -- An influential meeting has been held to discuss a proposed scheme for the provision of a public electric light supply for the district, which is one of the beauty spots of Danbighshire. The proposal is to form a company, with a capital of £5,000, made up of 4 per cent. pre-ference shares and ordinary shares of £1 each, which it is thought will be forthcoming without any difficulty, and the matter is relegated to a local Committee for further investigation of the financial aspect of the scheme.

-L.G.B. INQUIRY. - On March 17th an inquiry was held into the application of the U.D.C. for a loan of £600 for ervice connections, mains and meters, and £142 excess expenditure. There was no opposition.

Henley-on-Thames.—Prov. Order.—The T.C. has decided to oppose the application of the Reading Electric Supply Co. for power to extend its lighting order to the borough.

High Wycombe. - RESTRICTED LIGHTING. - The T.C. having asked the Electric Light Co. for a reduction in the charge for reurrent for arc lamps in view of the reduced lighting now being given. the company has allowed a rebate of 1d. per unit from January 1st last. The present scale of reduced lighting saves seven units per hour, and the allowance for six months will be approximately £27.

Huddersfield.—For the second year, the Electricity Committee has transferred to the borough rate an amount equal to the produce of 1d. in the pound, after making full provision for depreciation. The tramway department has provided an amount equal to 4d. in the 2 in relief of the rates, or id. more than last year, whilst transferring at the same time substantial sums to the depreciation and contingencies fund.

- EXTENSION SCHEME. - The Electricity Committee, on the advice of Mr. H. B. Hooper, L.G.B. Inspector, has decided to modify its scheme for extending the generating plant, and to defer that portion recommending the installation of a 5,000 kw. turbine unit and condenser, also one boiler and the coalhandling and water-cooling plant, thus reducing the sum required to £26.445.

Application is to be made to the L.G.B. for sanction to a loan of £20,000, and the balance is to be paid out of reserve

-At the meeting in London of the Mysore Gold Mining Co. it was stated that owing to prolonged drought, the electric supply from the Cauvery plant was restricted during the year, and the reserve steam plant had to be used.

The Mysore Government is now building a dam on the Cauvery

River to provide sufficient storage to prevent a similar state of affairs in the future.

Lees. - Messrs. J. B. Lord & Sons have asked the U.D.C. to sanotion their having a supply of electricity for lighting from Oldham, and have been informed that they must first make application to the Oldham T.O., who could then apply for the consent of the U.D.C.

- FULHAM. - The Electricity Committee London. .

the addition of 5 per cent. to all accounts rendered.

HACKNEY.—The Finance Committee of the B.C. recommends that the estimated surplus of the electricity undertaking for the year ending March 31st, amounting to £1,952, be transferred to the credit of the general rate fund.

WESTMINSTER.—The City Council has decided to continue the contracts with the Charing Cross, the Metropolitan, and the St. James's and Pall Mall Companies for the supply of energy to the Council's buildings.

Morecambe. - NEW, PLANT. - The T.C. has decided to purchase a new evaporative condenser for the electricity works to cope with the increasing demands.

Nantwich.—The R.D.C. has decided to consent to the application of Crewe T.C. for an order enabling it to supply electricity to Wistaston. Current will be supplied at a price equal to gas at 2s. 8d. per 1,000 cb. ft, which is less than the present charge for gas.

Newton Abbot.—RESTRICTED LIGHTING.—Owing to the restricted public lighting, the Urban Electric Supply Co. has offered the U.D.C. a reduction in the lighting account of £200 to the end of the year.

-The Electricity Committee has Perth.-New Plant.considered several offers for plant for the extension scheme at the electricity works, but on account of the cost has been unable to come to any decision. The engineer is to visit the Midlands to inspect a generating plant which has been in use only a short time, and can be obtained on satisfactory terms.

Salford. - RATEPAYERS AND WAR BONUSES .- The decision to grant war bonuses to Corporation employés in certain de-partments was criticised at a meeting of the local Ratepayers' Association on Monday. As a class (said one of the speakers) some Association on monday. As a class (said one of the speakers) sime workmen were being paid 7s. a week more at the present time than was being given for similar labour by the best employers in the district. It was urged that the Corporation should, by means of adequate reserve funds, have consolidated its position to enable it to deal with any situation that might arise.

Tunbridge Wells.—L.G.B. Inquiry.held on March 16th into the application of the T.C. for a loan of £7,520 for electricity purposes. Provisional tenders have been accepted, with increases on the engineer's estimates amounting to £617, and this sum was asked to be added to the loan applied for. The Inspector (Mr. H. R. Hooper) suggested that no extensions should be carried out until the war was over, but the town clerk urged that the application should not be refused, but adjourned.
Mr. Hooper said he did not think he could pledge the Board to do
that, and urged that the works should be carried on as at present, certainly for another year. The town clerk said he could not withdraw the application without a special meeting of the Council, and he again suggested that it should be postponed. Mr. Hooper and he again suggested that it should be postponed. Mr. Hooper replied that postponement would carry the suggestion that the L.G.B. agreed with the principal that the extensions were necessary, and he did not think it would take that view.

U.S.A.—ELECTRIC COOKING.—In view of the success attained with all-electric cooking in a large apartment house on Irving Street, Worcester, Mass., built by the same concern, the Colonial Real Estate Co. of that city will equip a new eighteensuite apartment now under construction with electric ranges. As in the Irving Street property, no coal ranges will be provided, and service will be supplied through a separate meter at a rate of from 3 cents to 4 cents per kw.-hour. In the latter suites the monthly cost of energy for domestic cooking has averaged from \$2.50 to \$3 per family, three persons constituting the average household. The Colonial Co. is so much pleased with the results of electric cooking that all future buildings erected by it for apartment service will be provided with electric ranges exclusively.—Electrical World. suite apartment now under construction with electric ranges.

West Ham.—Proposed Loan.—The electrical engineer has reported on the position with regard to loan sanctions as influenced by the war, and recommends an application for a strictly limited amount in regard to one of the sanctions which is nearly exhausted and estimated to be sufficient for 12 months. The Electricity Committee has accordingly agreed to make application for a loan sanction in regard to £3,000 for mains work, but the expenditure is only to be incurred as required in connection with additional fresh demands for electricity supply.

Willesden. — The U.D.C. has been recommended to afford a stand-by supply to the Guardians, for a period of not less than seven years, at an annual charge of £45 plus 2d. per unit for energy supplied. In view of the reduction of street lighting, and the number of lamps in stock, the Electricity Committee has decided to suspend the resolution allocating £500 per annum for the renewal of arc lamps for the year 1914-15, and to assign from the current year's expenses only the actual amount expended in renewals (£30).

Winchester.—January Outputs, &c.—With reference to our note in last week's issue, the outputs given were, of course, for the last and previous Januarys, and not, as stated, year's outputs: the estimated output for the year ending March 31st next is over a million units, an increase of at least 50 per cent, since the Corporation took over the undertaking from the Electric Light Co.

Windsor.—Sewage Pumping.—The R.D.C. is obtaining expert opinion as to the best means of sewage pumping for the Ascot district main drainage scheme. The systems to be considered are:—(1) Electricity; (2) Diesel engines; (3) semi-Diesels; (4) suction gas.

Wombwell.—L.G.B. INQUIRY.—An inquiry has been held into a proposal to supply gas to Great and Little Houghton. On behalf of the Little Houghton Council, it was stated that the Houghton Main Colliery Co. proposed to light the place by electricity, though it was admitted that nothing had been done during two years.

#### TRAMWAY and RAILWAY NOTES.

Aberdeen.—P.A.Y.E. SYSTEM.—The T.C. has decided by 19 to 12 to discontinue the P.A.Y.E. system of cars on the tramways. In the course of discussion it was suggested that the fare question had been confused with the matter of certain constructional features to which objection was taken. The Council also discussed at length the question of the tramway manager's patents, &c., the matter being finally dropped.

Bristol.—TRAMWAY PURCHASE.—The Tramways Option Committee of the Council, on the suggestion of Sir John Snell, has instructed Mr. C. P. Sparks, consulting electrical engineer, Mr. P. Addie, the city valuer, and Mr. L. S. McKenzie, the city engineer, to make an independent joint valuation of the portion of the Bristol tramway undertaking which is purchasable by the Corporation, on what are known as "tramway terms." The option to purchase arises during the present year.

Cheadle and Gatley.—TRAMWAY LEASE.—The U.D.C. has agreed to lease the tramways to the Stockport T.C. from March 4th, 1904, to March 3rd, 1925, with an option to renew the lease at the expiration. Provision is made for electrical equipment.

Continental.—Spain.—Application has been made to the Spanish Government for a concession for the construction and working of an electric tramway between the town and harbour of Valencia.

Dundee. — TRAMWAY ARBITRATION. — Evidence was heard in Edinburgh in the arbitration between the Dundee, Broughty Ferry and District Tramway Co. and the T.C. on the price to be paid for the portion of the district tramway line between the eastern boundary of Dundee and the western boundary of Broughty Ferry as they existed in 1904. The claim by the company is for £14,500, and the T.C. maintains that this sum is greatly in excess of the value of the subjects in question. Mr. Stephen Sellon, in his evidence, put the total value at £17,000. Mr. George Balfour, the managing director of the company, was examined on the various items of the claim. He said the figure for Parliamentary expenses was £1,100. The cost of raising capital was put at £3,000 by Mr. Sellon; he put it at £1,500, representing 10 per cent. on £15,000. It cost him more to raise the capital in 1905. The inquiry was adjourned until May 7th. The claim of £980 for overhead equipment has been settled for £640.

Edinburgh.—A conference took place last week between a Sub-Committee of the Tramways Committee and the directors of the Colinton Tramways Co. regarding the Colinton Tramways and the lines which the Corporation is seeking powers to construct.

Glasgow.—Female Conductors?—A deputation of the Women's Suffrage National Aid Corps has approached the Tramways Committee in support-of-a-proposal that, in view of the scarcity of men to act as car conductors, owing to the war, women should be employed in that capacity at the same wages and on the same conditions as men. Mr. Dalrymple has reported that he is still 300 men short of his regular staff, and that conductors and motormen are working practically seven days a week.

Liverpool.—YEAR'S WORKING.—The annual report of the Corporation tramways for the year ending December 31st shows that the revenue amounted to £722,307 and the operating

shows that the revenue amounted to £722,307 and the operating costs to £473,678, leaving a gross profit of £248,629.

The net profit was £134,821, a decrease of £19,341 compared with the year 1913, this being attributed to an increase of £11,000 in rates and taxes, an increase of £10,000 in wages account (including allowances to dependents of employés who are at the front), and the supplying of 1½ millions of free passes (representing a value of £8,232) to soldiers and sailors. Although the profit had decreased, the contribution in relief of the rates was the same as last year. The number of passengers carried during the year was 145,656,374, an increase of over 1½ millions compared with the previous year; the receipts were £684,026, an increase of £6,145, and the mileage 13,657,888, an increase of 215,283 miles.

London.—L.C.C.—The Highways Committee recommends that, owing to the difficulty which is experienced in obtaining suitable men for motormen and conductors, and because learners are apt to leave before their training is completed, the pay of motormen and conductors, while learning, be 3s. 6d. per day for a period of six weeks, as a temporary measure during the continuance of the war.

Morecambe.—Upon the recommendation of the Tramways Traction Committee, the Council has decided not to proceed with the investigations which had in view the adoption of some system of power traction to replace the present horse vehicles. This decision has been arrived at on account of the increased cost of materials consequent upon the war.

Musselburgh.—Tramway Dispute.—At the instance of the Industrial Commissioners, Prof. Lodge, last Friday, held an inquiry into the circumstances of the Musselburgh tramway "lock-out." At the close it was stated that a deadlock had been reached on the question of the reinstatement of the six dismissed men.

Newcastle-on-Tyne. — Tramway Estimates.—At a recent meeting of the City Council, Ald. Rodgers discussed the position of the Committee's estimates in view of the demand by the tramway men, in common with other municipal workers, for an advance of 5s. per week on account of the high cost of living and the high rents. Since the estimates of the Tramways Committee were prepared, he said, everything had changed. The actual income for the closing year would be £280,000. During the coming year it was proposed to open the Newburn and Forest Hall lines, and the income had been estimated at £282,000. The traffic expenses for the last year was estimated at £72,000, but that had been considerably increased by concessions to the men in July last, amounting to £5,000. He mentioned other increased expenditures, and remarked that, apart from the bonus given by the Tramways Committee to the rates, the undertaking was paying £16,900 in rates. The first surplus at the end of next year, he estimated, would be £121,900, as against £110,250. From that sum £82,500 had to be taken for interest and redemption of loans, leaving £39,400 at the end of the year. They were paying the dependents of the men who had gone to the Front, the original estimated cost of which was £8,000, but since then the allowances had been increased, and that amount had risen to £9,500.

An advance of 5s. per week to the tramway-men would mean £18,000. The various charges against the undertaking, in view of the increases asked for, and with the £18,000 for the rates, totalled \$64,236. To meet that they had a surplus of £39,000 add and

An advance of 5s, per week to the tramway-men would mean £18,000. The various charges against the undertaking, in view of the increases asked for, and with the £18,000 for the rates, totalled £64,236. To meet that they had a surplus of £39,000 odd, and that would result in a deficiency of £24,824. Any bonus granted to the men would have to come out of the £18,000 voted to the rates. In any case, the tramways would show an adverse balance next year. After discussion, it was decided to give war bonuses of 2s, 6d, 1s, 6d, and 1s, for six months from April 1st.

South Africa.—Judging by the South African papers, Germiston's railless traction venture has so far not realised expectations. It would appear that the system is running at a loss of £60 or so a week, exclusive of loan charges which are stated to be £3,500 per annum. A week's receipts averaged 7'7d, per c.m., and expenditure 12'6d. The Boksburg undertaking for January showed a gross surplus of £62; the T.C. is endeavouring to get power at industrial rates, when it is estimated that all charges will; be covered.

Warrington.—The Corporation has decided to pay a war bonus to all employés in receipt of wages of and exceeding £1, but not exceeding £2 per week.

West Ham.—PROPOSED LOANS.—The T.C. is to apply for sanction to borrow £3,000 in respect of the difference between the revised estimate for the purchase of 15 bogic cars and one single-truck car, and the amount already sanctioned; and £10,000 in respect of car equipments, after having deducted £18,000 to be provided out of the reserve fund.

### TELEGRAPH and TELEPHONE NOTES.

A Daring Cable-Cutting Exploit.—Reuter recently reported that on the 7th inst. H.M.S. Amethyst was entrusted with reported that on the 7th inst. H.M.S. Amethyst was entrusted with the difficult task of cutting the telegraph cable connecting Kilid Bahr with Chanak, at the Narrows of the Dardanelles. She reached her objective undetected, lifted and cut the cable, and started on her return journey before she was discovered. She then had to run the gauntlet of the guns of the forts on both sides of the Narrows, and became the target for a veritable hell of fire. She raced at full speed towards the entrance of the Straits, all the time exposed to heavy fire, but although frequently hit, she succeeded in getting beyond the range of the guns after a very narrow escape.

Direct Telegraphy to Russia.—It is reported from Stockholm that rumours are in circulation there concerning a direct telegraphic connection between Great Britain and Russia, which is alleged to have been established by an English cable steamer in January, 1915, from the North of Scotland round Scandinavia alleged to have been established by an English cancel Scandinavia January, 1915, from the North of Scotland round Scandinavia to the Russian coast, where a continuation to the Russian telegraph system was effected by means of a provisional overhead line in a southwardly direction. It is considered to be noteworthy in this connection that the Russo-English telegraph service vid Norway has ceased since January 20th. On the other hand, the Swedish telegraph director Curman is credited with the statement that a high official of the Danish telegraph administration on returning recently from Russia had informed him that the cable in question had actually been laid. A diminution of the telegraph in question had actually been laid. A diminution of the telegraph service between England and Russia, however, has not been recorded in Stockholm.

Grangemouth.—Owing to fire in a building, the lower part of which was occupied by the local telephone exchange, telephone communication with the town was entirely suspended for several days recently to permit of the necessary repairs.

Norway,-The town of Tönsberg has adopted the automatic telephone system of the Western Electric Co., with satisfactory results.

Telegraph Messengers.—The experiment of employing girls in the capacity of telegraph messengers in the Liverpool suburban post offices is being tried. The demand for boys greatly exceeds the supply, and the problem of Liverpool girl unemploy-

#### CONTRACTS OPEN and CLOSED.

#### OPEN.

Aberdare.—April 6th. U.D.C. Motor-generators or converters, one H.T. switchboard and L.T. panels, and one H.T. feeder pillar. See "Official Notices" March 19th.

Aldershot.—April 20th. U.D.C. One 400-KW. D.C. turbine set, complete with surface condenser and circulating pumps, &c. One water-tube boiler with chain-grate stoker. See "Official Notices" to-day.

May 4th, Steam and other pipework. Water-softening plant. See "Official Notices" to-day.

Australia.—Melbourne.—April 28th. Electric lighting material for car repair shops at Jolimont, including steel conduits, cable, switches, lampholders, &c., and trucks of 4,000 lb. capacity, driven by storage batteries. Copies of the specification can be seen at the Commercial Intelligence Department of the B. of T., Basinghall Street, E.O.

April 19th, 13,560 yards of lead-covered cable for the City Council. See "Official Notices" to-day.

April 19th. 13 tons of bare hard-drawn copper cable for the City Council. See "Official Notices" to-day.

June 2nd. Electric lighting material for cars (Contract 28,187).

Tender box, Railway Offices, Melbourne. Particulars at Contractors' Room, Spencer Street. Deposit ½ per cent. of amount of tender.

QUEENSLAND.—June 1st (instead of March 16th). Switchboard for Warwick. See "Official Notices" to-day.

Bray.—April 6th. U.D.C. Stores for electric light works. See "Official Notices" March 19th.

Bridgend.—April 8th. U.D.C. 4 nator. See "Official Notices" March 19th. 400-KW. steam alter-

March 30th. U.D.C. Small steam coal for the power station. Forms of tender from the Manager, Electricity Works.

Brighton.—April 12th. Cordenser. See "Official Notices" to-day. Corporation. Surface con-

Carlisle.—March 31st. Corporation. Twelve months' supply of jointing materials, oils, and general stores. Forms, &c., from City Electrical Engineer, Victoria Viaduct.

-March 29th. The Corporation Electricity Dundee.-

Department invites tenders for stores.

March 30th. Corporation Electricity Department. Centrifugal pumps, and laying cast-iron pipes.

Edinburgh.—March 29th. Corporation. Three, six or twelve months' supply of insulated cables, are lamp carbona, fuse boxes, meters, &c., for the Electricity Supply Department. Forms of tender (10s.) from the Electrical Engineer's office, Dewar Place.

April 12th. Corporation. Water-tube boilers for Portobello Supply Station. See "Official Notices" March 19th.

Harrogate, -March 29th. Twelve months' supply of electrical fittings and sundries for the Harrogate Wells and Bath Department. Forms of tender from F. J. C. Broome, General Manager.

Glasgow.—March 24th. Electric lighting installation at Shakespeare Public School, Maryhill, for the School Board. Specification from the School Board Offices, 129, Bath Street.

-March 31st. L.C.C. Installation, 218 wiring London.points, 265 lighting points, at Derington Road Elementary School, Lower Tooting, S.W. See "Official Notices" March 19th.

St. Panchas.—May 11th. Constructional steelwork at power house, for B.C.

Manchester,-March 29th. The Lancashire and Yorkshire Railway Co. invites tenders for 12 months' supplies of signal, telegraph and electric fittings (Section 32), signal, telegraph and electric light wires (Section 33), steel plates, Siemens (Section 39) steel sheets, Siemens and Electrical (Section 41). Particulars and forms of tender from Mr. Waring, stores superintendent, Osborne Street, Manchester.

New Zealand.—Wellington.—April 30th. Supply of a three-unit exciter set and 1,600-kw. generator for the Lake Coleridge Hydro-electric scheme. A copy of the specification can be seen at the Commercial Intelligence Department, B. of T., London, E.C.

Sheffield.—April 12th. Supply of motor-van (petrol or electric) to carry one ton, for the Corporation. Specification (10s.) from the Cleansing Superintendent, Town Hall.

Spain.—The Spanish Post and Telegraph authorities in Madrid are at present inviting tenders for the erection of a tele-phone line between Barcelona and La Junquera, a distance of about

Sunderland.—April 1st. Corporation. Electrical stores, overhead line, &c., for the Tramway Department. Forms of tender from Mr. A. R. Dayson, Tramway Manager.

Whalley.—April 5th. Lathes, vices, electrical instruments, &c., for the County Asylum. See "Official Notices" to-day.

#### CLOSED.

Aberdare. — The U.D.C. Electricity and Tramways Departments have placed contracts for 1915-16 as follows:

Cables, joint-boxes, &c.—Callender's Cable & Construction Co., Ltd.
Meters.—Landis & Gyr, Ltd.
Paints.—Navigation Paint Co., Ltd.
Lubricating and other oils.—Vacuum Oil Co., Ltd.
Uniforms.—Jas. Smith & Co. (Derby), Ltd.

Australia.—The following contracts have been placed:—

Australia.—The following contracts have been placed:

P.M.G.'s Department, Sydney.—
75 miles of twisted-pair outside distributing wire, £968.—B.I. & Helsby Cables, Ltd.
4,000 lineal tt. of glazed earthenware four-duct conduit, £921; 12,000 ft. of nine duct ditto, £2,187.—Brunswick Brick, Telegraph & Pottery Works Pty.

One naut telegraph cable, single core, £141; one ditto (item 5), £416; 15 nauts cable, ditto, £218.—Siemens Bros. Dynamo Works, Ltd.
8 miles of paper-insulated lead-covered cable, 52 pairs, £783; 5 miles ditto, 208 pairs, £2,996; 1 mile ditto, 312 pairs, £790; 94 miles ditto, 416 pairs, £10,299; 2 mile ditto, 208 pairs, £474.—B.I. & Helsby Cables, Ltd.
4 miles of paper-insulated lead-covered cable, 260 pairs, £1,638.—Noyes Bros. (Sydney), Ltd.
8 miles of paper-insulated lead-covered cable, 28 pairs, £1,020.—Laurence and Hanson Electrical Co., Ltd.
8 miles of paper-insulated lead-covered cable, 28 pairs, £1,020.—Laurence 39 pairs, £828.—W. T. Henley's Telegraph Works Co., Ltd.

Aust. Mining Standard.

Aust. Mining Standard.

N.S.W. Public Works Department.—
Electrically-driven centritugal pump, for Homebush abattoirs, £763.—
Haes & Eggers.

Prahran & Malvern Tramways Trust (Victoria).— Tudor battery, £2,817.—Elder, Smith & Co. The following contracts were recently given out by the Commonwealth P.M.G. s Department:—

10,400 English metal-filament lamps.—Australian General Electric Co.
80 tons of H.D. copper wire, for Queensland, £2,429.—Laurence and
Hanson, Ltd.

Hanson, Ltd. Telephones and other apparatus.—James Paton & Co. 200 detectors, £520.—British General Electric Co., Ltd.

Barnsley.—The Education Committee has accepted the tender of the Corporation Electricity Department, at £44, for laying cable from the sanatorium and installing electric light at the new open-air school.

Blackburn.—With reference to the notice appearing in our last issue, we are informed that the contract for A.C. meters has been placed with the British Westinghouse Co., Ltd. Messrs. Chamberlain & Hookham will supply only the D.C. meters.

Coventry,—The Corporation Electricity Department has placed a repeat order with Messrs. Ed. Bennis & Co., Ltd., for eight chain-grate stokers, 7 ft. wide  $\times$  13 ft. 6 in. centres, for B. & W. boilers.

East Ham.—A short while ago the Town Council accepted the tender of Mesars. Allen & Son to provide an electric motor for the sewerage works, for £620. The firm have now written to the effect that they cannot supply the apparatus for less than £682. The responsible Committee has agreed to the increased price.

Government Contracts.—The following tenders have been accepted during the past month by the Government Departments named :-

Post Office.

Annual contracts for laying conduits (short lengths, not continuous).—City of London, J. A. Ewart, Ltd.; Finsbury and Holborn, O. C. Summars; Westmioster and Chelses, F. G. Brummell.

Laying ducts and pipes.—Boxmoor, May, Mortimer & Co.; Burgh Heath, J. Mowlem & Co., Ltd.

Telephone exchange equipment, automatic order wire, selection system.—Avenue Exchange, Siemens Bros. & Co., Ltd.

Telephone exchange equipment extensions.—Greenock, Western Electric Co., Ltd.; Streatham, Western Electric Co., Ltd.; Victoria, S.W., Peel-Conner Telephone Works, Ltd.

Protective apparatus (lightning and power).—British L. M. Ericsson Mfg.Co., Ltd.

Telegraphic apparatus.—Murray Printing Telegraph Systems; Park Royal Eng. Works, Ltd.; Reid Bros. Engineers, Ltd.; Siemens Bros. and Co., Ltd.

Telephonic apparatus and parts.—Automatic Telephone Mfg. Co., Ltd.

Copper boltz.—T. Bolton & Sons.
Electric lighting material.—J. Stone & Co.

CROWN AGENTS FOR THE COLORIES.

Insulators.—Bullers, Ltd.,
Parts for telegraph poles.—F. Morton & Co., Ltd.
Telegraph poles.—Bullers, Ltd.
Copper line wire.—Shropshire Iron Co., Ltd.

-The Parochial Committee has accepted the tender of the B.I. & Helsby Cables, Ltd., for the electrification of the pumping station and sewerage works, the amount for the pumping station being £159, and for the sewerage works £186.

Huddersfield,-The tender of Messrs. J. H. Taylor and Co. for electricians work in connection with Bradley Sanatorium has been accepted. The Electricity Committee has accepted the tender of Mr. Wm. Wood for supply of coal.

-The Education Committee proposes to accept the tender of Messrs. Matthews & Yates, Ltd., at £90, for installing silent-running fans at the Old Montague Street School, Whitechapel.

The tender of Messrs. Toy & Winslow has been accepted by the Metropolitan Asylums Board, at £70, to execute sundry electrical works at the South-Western Ambulance Station.

-The Highways Committee reports that all the tenders received for the supply of two additional 8,000-kw. turbo-generators for the Greenwich generating station were submitted subject to the model conditions of contract for electrical works adopted by the Institution of Electrical Engineers, which differ in many respects from the Council's standard conditions of contract, some of which are based on standing orders. The Committee has been in communication with the British Westinghouse Electric and Manufacturing Co., Ltd., whose tender for £62,003 was accepted with a view to the modification of the Institution's model conditions of contract to bring them as far as possible into line with the Council's standard conditions. A modified form of contract has now been agreed as a special case, and without prejudice to the future consideration of the whole question, and, as the pay-ment clause differs somewhat from the terms of that provided for in Standing Order No. 295 (d) (1) it will be necessary for the Council to suspend its operation. The Committee therefore

That the operation of Standing Order No. 295 (d) (i) be suspended, in order that the contractor be entered into with the British Westinghouse Co. may provide for the undermentioned payments to be made to the company in respect of the work—(i) monthly payments of 80 per cent. of the contract value of the plant delivered or work executed on the site; and (ii) further payments in respect of each distinct section of the works of 30 per cent. of the contract value of the work executed on the site upon completion of the erection of the plant, 10 per cent. at the expiration of one month after the plant shall have been taken over by the Council, and the remaining 10 per cent. at the expiration of the period of maintenance.

The tender of Messrs, Siemens Bros, Dynamo Works, Ltd., has been accepted for carbon-filament lamps for the ensuing 12 months.

BERMONDSEY.—Messrs. Chamberlain & Hookham's tender for meters and time switches has been accepted by the Council for the coming 12 months.

FULHAM.—The prices quoted for the supply of electrical and engineering stores for the ensuing year show a general advance of from 10 to 20 per cent., and the Electricity Committee therefore recommends that for the ensuing year no annual contracts be entered into for the above-mentioned stores, but that the borough electrical engineer be instructed to purchase in the open market at the lowest price obtainable as and when required.

ST. PANCRAS.—The Electricity Committee has further con-ST. PANCRAS.—The Electricity Committee has further considered the question of the acceptance of the tender for the supply of carbons for the ensuing year, and as there is in hand a sufficient stock of carbons for four months the General Electric Co. were asked whether the price named would hold good for a four months' instead of a year's supply. The company are prepared to give a four months' supply of open-type carbons at the prices quoted, provided the full 12 months' supply of fiame carbons is taken. This would represent £475 for fiame carbons and £511 for open-type carbons. The Committee recommends the acceptance of the offer.

Manchester.—The Corporation Electricity Department has placed a repeat order with Messrs. Ed. Bennis & Co., Ltd., for the relinking of two pairs of chain grates of another make, at the Bloom Street power station, with "Bennis" patent chain-grate

Newport (Mon.)—The B. of G. has accepted the tender of Messrs. R. Alger & Sons, for E.L. fittings.

Rawtenstall.—The T.C. has contracted with Messrs. J. Morris & Co., for a supply of 1,500 to 2,000 tons of coal to the electricity works, Hareholme.

Sunderland.—The Times states that Messrs. Vickers, Ltd., are supplying two turbo-alternators of 5,000-kW. capacity each for the Philadelphia power station, near Sunderland, the contract for which was originally given to the A.E.G.

Walthamstow.—The electrical engineer has reported with reference to the supply of arc lamp carbons, and has been with reference to the supply of arc lamp carbons, and has been instructed to at once accept the quotation of the General Electric Co., Ltd., for the supply of 25.000 pairs of 10-ampere size carbons, at £8 1s. 5d. per 1,000 pairs, and 50,000 pairs 5-ampere size carbons, at £4 16s. per 1,000 pairs; 200 tons of Griff peas coal and 100 tons of High Park nutty slack coal have been purchased from Messrs. Myers, Rose & Co., Ltd., and Messrs. G. Hinchliffe & Co., respectively. The District Council is recommended to authorise the surveyor to hire an electrically-propelled dust van from the Edison Accumulators Co., Ltd., for one week on trial, at a cost of Edison Accumulators Co., Ltd., for one week on trial, at a cost of £6, the Council to provide the current.

West Ham.—The tender of the Fuller Electrical and Manufacturing Co., Ltd., has been accepted for the supply of motors for the sales department during the ensuing 12 months. The existing contract for the supply of cables terminates on March. The electrical engineer has been in negotiation with the present contractors, the British Insulated and Helsby Cables, Ltd., who are prepared to grant a concession in regard to low-tension service cables if the contract be extended for a further period of three years. In view of the fact that the cables under this contract annulsed on a cliding scale in regard to the price of tract are supplied on a sliding scale in regard to the price of copper and lead, the Committee has decided to accept the offer.

#### FORTHCOMING EVENTS.

Royal Institution of Great Britain,—Friday, March 20th. At 9 p.m. At Albemarie Street, W. Paper on "Experimente in Slow Cathode Bays,"

Albemarle Street, W. Paper on "Experiments in Slow Cathode Rays," by Prof. Sir J. J. Thomson, F.R.S.

Saiford Technical and Engineering Association.—Saturday, April 3rd. At 7.p.m. At Royal Technical Institute, Peel Park. Paper on "Lifting Machinery," by Mr. D. Riley.

#### NOTES.

Our Next Issue. - Next Friday being Good Friday, the ELECTRICAL REVIEW will appear on Wednesday morning. All matter for our Editorial and advertisement pages should be in our hands at the earliest possible moment.

The Electrical Trades Benevolent Institution.-The Electrical Trades Benevolent Institution.—
The Committee has resolved to call the annual general meeting of this Institution for Monday, April 19th, at 6.30 p.m., at the Institution of Electrical Engineers. Mr. E. Garoke will be in the chair. The time mentioned has been selected in order to afford a better opportunity of being present to those interested in the Fund. It is thought that it will be convenient to many subscribers and friends to "drop in" at the Institution on their way home from their offices. We hope that the attendance will justify the change; also that it will show that in these trying days the electrical world has time and thought to spare for so deserving an organisation and Fund, the claims upon which must inevitably be larger in the near future. in the near future.

Copper. - Some difficulty arises in endeavouring to appreciate the copper position at the present time, as comparisons with pre-war conditions, though of some interest, cannot give an indication of the general tendency. The statistics for mid-month, now to hand, as tabulated by Messrs. H. R. Merton & Co., require, now to hand, as tabulated by Messrs. H. R. Merton & Co., require, as is pointed out, to be considered in relationship to the fact that the quantity of stocks at Havre can now be ascertained, whereas for the past seven months it has been given, as an estimate, at pre-war figures. This makes an apparent falling-off in European supplies of 5,973 tons, since the end of last month. English supplies, however, have only decreased by 447 tons. In detailed supplies we find that European arrivals from North America during the fortnight ending March 15th were 16,184 tons, which approaches very closely to the pre-war average of 17,200 tons. Spain and Portugal, even after the heavy consignments of last month, supplied this country and France with a quantity slightly in excess of the pre-war average.

last month, supplied this country and France with a quantity slightly in excess of the pre-war average.

The quantity from countries not specifically mentioned, which has been very strong recently, is again high at 3.576 tons. Chile shipments were low, and Australian, after two heavy months, show only 1,250 tons against a pre-war average of 1,655. The extraordinary thing about the figures is, of course, that it is possible to compare them with pre-war figures at all. The supplies for the first half of March are less than 4 per cent, lower than the average pre-war half-monthly supply. The impression given by the figures is that a very little stimulus in the way of extra price would raise supplies again to the normal quantities.

Patents and Alien Enemies.—Mr. G. H. Wilson, electrical engineer, of the Manchester Armature Repair Co., Pendleton, Manchester, applied on Tuesday in the Patent Court set up to deal during the war with the patents of alien enemies, for set up to deal during the war with the patents of alien enemies, for a licence to manufacture self-insulating aluminium field coils for electrical motors, under five German patents—namely, Nos. 10,457 of 1906, 2,711 of 1910, 20,634 of 1910, 9,941 of 1911 and 27,661 of 1912, held by the Spezialfabrik für Aluminium Spulen und Leitungen, of Frankfurster Str., Berlin.

Mr. J. G. Johnson represented the applicant; Mr. Courtney Terrell appeared for the patentee.

Mr. Johnson said the patent applied to field coils for electrical motors. These coils could be used in electric motor correspond to an electric motor correspond to a metal.

motors. These coils could be used in electric motor-cars and tram-cars, as well as industrial dynamos and motors. All the patents related to the manufacture of coils from aluminium instead of

copper.

Mr. Terrell said the film of oxide on the surface of aluminium Mr. Terreit said the nim of oxide on the surface of aluminium formed a natural insulation; that, however, was not entirely relied upon here. Sheets of insulating material were used, instead of insulation wrapped round the wire. The advantages of the aluminium coil were its lightness, durability and cheapness,

Mr. Wilson said the first patent related to the natural oxide; the rest were concerned with strengthening the oxide film. He employed 30 men at his works and had supplied 20 tramways. He had made about 300 aluminium coils. He had regular customers who otherwise would be forced to use copper coils. He could supply them with aluminium on more favourable terms. His firm wind other wise would be forest to use diper ones. His firm made armature coils for tramways and field coils generally. If he had a monopoly of the supply of aluminium coils, he thought he could sell 10 or 20 thousand pounds worth per annum, say, 5,000 coils. The Manchester tramways bought about a thousand coils per annum, at a cost of between £2 and £3 each. The price to sell of the average tramway coil was 10s, a coil cheaper for aluminium than for copper, roughly, ignoring the fluctuations in the price of copper which had coincided with the war. On the average number used by the Manchester Corporation the saving would be £700; he would offer them copper coils at £2 10s., aluminium at £2. He had a year's experimental agreement with the German firm dated August 1st, 1912, which entitled him to the grant of an exclusive licence from them to manufacture, sell or use electrical aluminium coils in the United Kingdom or the British Colonies, and negotiations for such exclusive licence were British Colonies, and negotiations for such exclusive licence were in progress when the war broke out. He paid the owners £100 on signing the first agreement, and was to have paid a further

£100 on signing the second.

Mr. Wilson offered a royalty of 5 per cent. on the selling price, and asked that the licence should date from the commencement

of the war.

The Controller said the Board of Trade would duly communicate with him as to his licence.

Electro-Harmonic Society.—The smoking concert on Friday last—the last of the season—was particularly successful, the audience enthusiastically encoring almost all the items. Sir John Snell presided, and just before the interval he took the opportunity to explain to the members that when last autumn, the question was raised whether the concerts should be held, the Committee decided, in his opinion very wisely, to continue them during the war. He understood that the previous concerts this season had been attended by large and enthusiastic gatherings, and he could quite understand it, if they were as good as this one; he entirely dissented from the view that such concerts should be abandoned, believing that our gallant comrades at the front would desire that they should be continued. He was present in the dual capacity of President of the Institution of Electrical Engineers and hon, treasurer to the Society; the latter was not a very onerous position, as the bulk of the work was done by Mr. Lane. The Society had gained 55 new members and lost only 58, in spite of Society had gained 55 new members and lost only 58, in spite of the war, and the membership now stood at 661, a very good result; he hoped those members who had not yet contributed to the funds would do so at their early convenience. In a third capacity, as a member of the Society, Sir John pointed out how much they were indebted to their hon musical director, Mr. T.-E. Gatehouse, for drawing together the talented artistes and organising these splendid entertainments: he also referred to the enormous amount of work done for the Society by Mr. W. E. Lane, their hon, secretary, to whom, with Mr. Gatehouse and some other members, the thanks of the Society were due, and to whom they were obliged for that harmonious gathering.

An unusual feature of the evening was the presence of an orehestra from the London Symphony Players, whose rendering of the Allies' National Anthems and various patriotic and other selections was heartily appreciated.

selections was heartily appreciated.

Preferential Rates.—It appears that the question of charges for electricity used for photo-printing has cropped up at Ilkeston, but this time on the point of preference as between two men in the same line of business. An Ilkeston photographer named W. E. Attenborough, writing to the Ilkeston Pioneer, stated that he had threatened to commence proceedings against the Town Council for "undue preference" unless within 48 hours the Corporation agreed to charge him at the same rate for electricity for his photographic lamp as another photographer was charged. The Town Clerk called a meeting of the Electricity Committee, and the latter decided to accede to Mr. Attenborough's demand, besides refunding to him the amount overpaid, which came to £2 97. 8d. An earlier issue of the same paper states that Councillor W. Smith resigned the chairmanship of the Tramways and Electricity Committee, because he believed that an injustice had been done to Mr. Attenborough in charging him for energy at the lighting rate, and as he intended to assist that gentleman to obtain his rights, he felt he could not retain the position of chairman. Preferential Rates.—It appears that the question of felt he could not retain the position of chairman.

Councillor Smith is to be congratulated on his firm stand for justice and common-sense: the conversion of the Committee to his view completely justifies his action, which, however, should not have been rendered necessary. The Committee ought now in

fairness to re-elect him chairman.

Scottish Radium Factory.—The Times states that Dalvait, on Loch Lomondside, is to be the home of a new radium industry in Scotland. An old sawmill has been adapted for use as a factory for the extraction of radium and other rare metals from

their ores, and within the next few weeks a start will be made.

The promoter of the scheme is Mr. John S. MacArthur, a Scottish metallurgical chemist, who, about two years ago, began to make industrial experiments, working with ores from which the uranium and vanadium had already been extracted, and has already placed upon the market about 1,500 milligrammes of radium. In the new establishment he expects to be able to extract about 5 or 6 grammes

London Electrical Workers' Demands.—With reference to the last paragraph appearing in the communication appearing under this heading in our last issue, the Daily Telegraph says that the strike of electrical wiremen and armature winders working in the tramway department of the London County Council threatens to affect seriously the running of the tramcars. "The men are employed in repair work. About a year ago the electrical masters of London granted an increase to their wiremen of 1d. per hour, making the wages 10½d. The Tramway Conciliaof 1d. per hour, making the wages 10½d. The Tramway Conciliation Board advanced the men's wages ½d. per hour, to 10d., and the County Council took up the attitude that their wiremen are not covered by the agreement between the London electrical masters and the Union. Nearly 1,500 cars are owned by the Council, and of these over 40 are in the depôt for repairs at one time. With the exception of a few armature winders, who are till at wark all electrical workers are one trible to the extent of still at work, all electrical workers are on strike to the extent of nearly 100 men. The remainder of the winders are expected to join the strikers. The men are receiving strike pay from the Electricians' Federation, which was represented at the Government conference at the Treasury, where it was agreed that no strikes should take place.

Electrical Expansion in Germany.—The statistical seport published yearly by the German Union of Electrical Central Stations has again appeared, and covers the year 1912-13. The new volume contains complete particulars of the working of 364 installations, 70 of which, serving about 15,000,000 people, are located beyond the borders of the German Empire, and 294 serving about 30,000,000 people, are situated in Germany. The statistics about 30,000,000 people, are situated in Germany. The statistics show that the undertakings have a tendency to enlarge their network, especially in the rural districts, and to become "overland" systems, corresponding to our large power supply companies. This is confirmed by the yearly increasing number of stations serving more than two localities, there being 99 such in 1910; 132 in 1911, and 153 in 1912. The number of communities served was 4,153 in 1910, 4,722 in 1911, and 6,434 in 1912, which gives an average for 1912 of 40 communities per station. One of the stations serves a locality situated at a distance, as the crow flies, of 102 km., while 13 serve localities situated over 50 km. distant. The figures show that 29 per cent, have a capacity of 5,000 kw. and upwards, and they represent 81 per cent. of the total power installed, which is a proof of the constantly increasing centralisation of the production of energy. The energy sold increased from 313,000,000 kw.-hours in 1911 to 385,000,000 kw.-hours in 1912. Per 1,000 inhabitants, the establishments supplied represent a power of 35.7 kw. for lighting, 50 kw. for motors, and 31.8 kw. for light and motors, with a common tariff, that is any, about 100 kw. in all. The power used by the motors grows more rapidly than that for lighting, the proportion being in 1912 53.5 per cent. systems, corresponding to our large power supply companies. This 53'5 per cent.

53'5 per cent.

The energy sold per head of population yearly has grown from \$4'6 kw.-hours in 1910 to 43 kw.-hours in 1911, and 48'9 in 1912 per 1,000 inhabitants. The average sale price of the kw.-hour in 1912 was 45'1 centimes for lighting, and 18'5 for power.

The average total cost of production per kw.-hour sold was 10'65 centimes in 1912.—L'Industrie Electrique.

The liford Railway Accident. — Lieutenant-Colonel von Donop, the Board of Trade Inspector, in his report on the liford railway accident, which took place on New Year's Day, when a passenger train from Gidea Park to Liverpool Street was run into by an express from Clacton, states that it is certain that the signals were in the danger position when the express passed them, and it was to a mistake on the part of the driver of the express that the collision was due. The Inspector says: "This collision colored to the desirability of the provision of some arrangement for that the collision was due. The Inspector says: "This collision points to the desirability of the provision of some arrangement for giving a driver an unmistakable warning as to the position of his distant signal when he passes it. Several railway companies have already made trials of devices designed for this purpose, and on some lines such devices are already in use to a limited extent.

Institution and Lecture Notes .- Physical Society of London.—At the meeting held on March 12th a paper on "The Estimation of High Temperatures by the Method of Colour Identity," by C. C. Paterson and B. P. Dudding, was read by the former. Preliminary experiments were described in which the temperature of incandescent substances was estimated with a very fair accuracy by matching their colour with that of incandescent slames working at appropriate efficiencies. These had filament lamps working at appropriate efficiencies. These has previously been calibrated by comparison with a "black body These had over a large temperature range. The comparisons were made in the field of a Lummer Brodhun photometer, and the method was shown to give the correct result for the melting point of platinum.

A paper on "The Unit of Candle-power in White Light," by C. C. Paterson and B. P. Dudding, was read by the latter. The paper described the methods adopted at the National Physical Laboratory for minimising the difficulty of photometric aboratory for minimising the difficulty of photometric comparison of white lights of different hue. A series of six sets of electric sub-standards were described varying in the tint of the light radiated from that of the pentane lamp to that of a tungsten vacuum lamp operating at 1.5 watts per candle. The absolute value of the unit of candle-power had been re-determined, as had also the corrections for humidity and barometric changes, and the

probable existence of a temperature correction was discussed.

A paper, entitled "The Relative Losses in Dielectrics in Equivalent Electric Fields, Steady and Alternating (R.M.S.)," by Mr. G. L. Addenbrooke, was taken as read. After references to former work, especially on surface leakage, tables were given showing an intimate connection between the losses in steady and alternating fields and that the one could be residued from the other tables. fields, and that the one could be predicted from the other to a first

approximation. Curves of the losses in from 1 to 4 seconds up to 40 oyoles were given for specimen dielectrics. Above 8 to 12 cycles, both for "good" and "poor" dielectrics, these became rising straight lines. The salient features lay below about 16 cycles. The formula a + b n applied to all dielectrics for frequencies above about 8 cycles, but not below. Liquid dielectrics behave

above about 8 cycles, but not below. Liquid dielectrics behave similarly to solid with certain differences, particularly that for a given resistance the ratio of the steady to the alternating loss was less than with solids. For the dielectrics tabulated these losses varied in a steady field from 1 to 1,300,000, but the corresponding alternating losses varied only from 1 to 1,100. The difference was principally in the "good" dielectrics, the alternating losses was principally in the "good" dielectrics, the alternating losees in which at 40 cycles were vastly larger than those in a steady field, though they still appeared to be connected with them.

Institution of Electrical Engineers.—At the meeting of the MANGHESTER LOCAL SECTION on Tuesday last, Mr. W. B. Cooper's

paper on "Electric Cooking, Mainly from the Consumer's Point of View," was read and discussed.

Bristol Association of Engineers.—The concluding meeting of the Session 1914-15 was held on March 13th, when a paper on "Impulse Electric Clocks" was read by Prof. D. Robertson.

Northampton Polytechnic Institute.—The course of Advanced Lectures on "Electrical Instruments and Switchgear," by Mr. A. C. Heap, M.I.E.E., which last autumn was announced to be given at the Northampton Polytechnic Institute during this spring, had to be cancelled, as urgent engagements caused by the continuance of hostilities make it impossible for Mr. Heap to undertake it at the present time.

Electrical Association of Australia.—The annual meeting of the VICTORIAN SECTION was held at Melbourne in December. The report of the Council referred to the amalgamation of the Victorian and New South Wales Associations, to the licensing of wiremen, and other matters. The financial position is sound, and the number of members of all classes is 226. The election of officers for the ensuing year resulted as follows:—President, Mr. W. H. Alabaster; vice-presidents, Meesrs. F. A. McCarty and A. W. Kendall; hon secretary, Mr. E. H. W. Westwood. At the conclusion of the ordinary business a smoking concert was held.—Com.

Mr. O. W. Brain, M.I.E E., Chief Electrical Engineer for Railways Mr. O. W. Brain, M.I.E E., Chief Electrical Engineer for Railways and Tramways, N.S.W. Government, has accepted the position of president of the Electrical Association of Australia. Other officers are:—Vice-presidents, W. H. Alabaster, chief assistant electrical engineer, Melbourne City Council; W. H. Myers, assistant engineer, Electrical Branch, N.S.W. Government Railways and Tramways (president of the New South Wales Section); members of Council, Prof. Henry Payne (Melbourne University, Engineering Department), Mr. W. J. Newbigin (director, Adams & Co., Melbourne), Mr. H. R. Forbes-Mackay (city electrical engineer, Sydney), Mr. A. C. F. Webb, M.I.E.E. (consulting electrical engineer, Sydney).—Sudney Morning Herald. Sydney Morning Herald.

Appointments . Vacant,—Meter tester  $(\pm 2)$  for Barrow-in-Furness Electricity Department; assistant electrical engineer  $(\pm 125)$  for Aylesbury U.D.C.; jointer for Stretford U.D.C.; works fitter (50s.) for Rhondda Electricity and Destructor Works; junior assistant electrical engineers (15s.), for Newcastle-upon-Tyne Electric Supply Co. Particulars are given in our advertise-

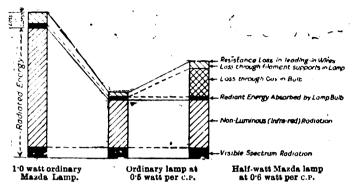

The Swedish Iron Ore Railway.—As previously announced, electrical working was commenced on January 19th on that particular section of the Swedish State Railways which proceeds from Kiruna to Riksgransen, and which has a length of 80 miles, the trains representing for the first time in Europe, it is claimed, loads of over 2,000 tons, inclusive of locomotives, trucks and iron ore. The working of the service takes place trucks and iron ore. The working of the service takes place under specially difficult conditions, as the line is the most northerly railway in the world, although it was formerly operated with steam locomotives, naturally with a considerably lower transport capacity and speed. The starting point of the railway lies nearly 87 miles to the north of the Polar Circle; a complete Polar climate prevails, and violent snowstorms occur, with degree of cold of 35°C. Nevertheless it is stated that down to the first week in March the working of the railway was fully maintained without any interruption. The railway is used for the transport of iron ore, which is mined at Kirnnayara near Kirnna to the Norwegian frontier. ruption. The railway is used for the transport of iron ore, which is mined at Kirunavaara, near Kiruna, to the Norwegian frontier, whence it is conveyed to Narvik, on the Atlantic Ocean, and each train of 40 ore trucks, each weighing 46 tons loaded, is hauled by two electric locomotives, of a combined length of 120 ft. The greatest tractive effect on the draw-bar is said to amount to about greatest tractive effect on the draw-bar is said to amount to about 40 tons. In addition to ore and passenger trains, one fast train runs in each direction daily, and forms one portion of the Northern Express between Stockholm and Narvik. The power station, which is 155 miles distant from the terminus of the railway, is situated at the Porjus Falls, where 40,000 H.P. have been brought into requisition for the operation of the line. Single-phase current, at 80,000 volts, is transmitted by overhead conductors to substitute arranged along the route, where it is converted to a rent, at 80,000 volts, is transmitted by overhead conductors to substations arranged along the route, where it is converted to a suitable pressure for the engines. As Sweden possesses but little native coal and is compelled to procure most of her supplies from abroad, the substitution of electric traction by the use of water-power yields certain economic advantages to the State from this point of view, as well as from others. Thus it is asserted that in the present case, and as compared with the former steam locomotion, it has been possible to increase the train capacity by 40 per cent, and the speed by 50 per cent, which are claimed to represent augmentation of 70 per cent, in the transport of iron ore. The work has been carried out by the Allmanna Svenska E.A.B. in association with a German firm. association with a German firm.

Energy Losses in Electric Lamps.—The accom-EMERKY LOSSES IN EMECTIC LAMPS.—Ine accompanying diagram shows very clearly how the new half-watt (gasfilled) lamps obtain their superior efficiency over the ordinary metal lamps. The columns in the diagram show the losses occurring in the ordinary vacuum lamp when operated at an efficiency of 1 watt per candle and at 0.5 watt per candle, as compared to the losses in the gas-filled or half-watt lamp when operated at an efficiency of 0.6 watt per candle. This diagram was recently presented in a paper before the Chicago Engineering Society by Mr. S. E. Doane.

The upright columns show how the energy is dissinated in the

The upright columns show how the energy is dissipated in the mps. The vacuum lamp when operated at an efficiency of 5 watt per candle shows smaller losses than the gas-filled lamp lamps. at similar watts per candle consumption, due to the energy loss in

the gas employed in the gas-filled lamp. As is well known, however, the ordinary metal (vacuum) lamp operated at such an efficiency as 0'5 watt per candle has a life of only a few hours.

On the other hand, the gas-filled (half-watt) lamp is able to operate at this high efficiency with satisfactory life, because of the neutral gas with which the bulb is filled. This gas, by preventing the evaporation of the filament when the lamp is operated at a high efficiency, enables the half-watt lamp to be produced with a commercial length of life. mercial length of life.

Energy losses due to the inert gas in the gas-filled lamp are, of course, unavoidable; but in spite of these losses, the diagram shows that the gas-filled or half-watt lamp makes a marked advance in efficiency over the ordinary vacuum lamp as used commercially. The actual energy losses in each type of lamp are shown in full detail, so that one can readily see how the remarkable gain in efficiency is obtained in the new lamps.

Russian Hydro-Electric Power.—The Inland Waters Department has prepared an explanatory report on the projected legal regulations for using Russian waterfalls, one of the leading motives in respect to which is the long-distance transmission of electrical power, having in view the exploitation of mines, electrochemistry and metallurgy, as well as the production of various materials of importance to agriculture. But above all the governing materials of importance to agriculture. But above all the governing idea is the supply of hydro-electric power for traction purposes, it being considered that the application of electric traction on rail-ways becomes more and more imminent. In European Russia it is calculated that 24 rivers can yield 1,000,000 H.P. without counting the rivers of the Caucasus; whilst the water power of Siberia has not yet been investigated. Some writers estimate the water-power of all Russia at 12,000,000 H.P.

The Russian Government has been moved to take this step by the large number of applications made to it for water rower con-

the large number of applications made to it for water power concessions, which began to be received in the nineties of last century.

The first consideration is to be the requirements of the Government, which points to the need for a general Governmental control; whilst it is recognised that almost every private concession involves some Government or public interest. The projet de loi is governed by the following essential conditions:—All water power must primarily be at the disposition of the Government, which may use it directly for the public good or lease it in the interests of industries requiring Government countenance. Any right conceded to private individuals may not be for an indefinite time as a private right; but must have a term to allow for reconsideration of the conditions and objects of the concession. Water power used for Government or public purposes must be considered as alien to anything in the form of private exploitation. It should always be under Government inspection, the Government being free to supress abuses, and to remove injurious consequences of a monopolistic character; and in the case of need the sources of supply of energy may be appropriated by the Government, which will make suitable compensation to concessionaires up to the final dates of their respective contracts.

Electrical Developments in Italy.—Treating the theme of "The Present and the Future of Electric Installations in Italy," the Rivista Tecnica d'Electricità comes to the following conclusions:—Premising that the war will occasion a long period of dear coal, as French, Belgian, German and Bohemian supplies will be interrupted, and only England and America will be able to furnish supplies, at enhanced prices, it concludes that a great opportunity will be afforded to substitute electricity generated from water-power for thermal sources of energy, and generally to enlarge and improve existing electric plants. According to the enlarge and improve existing electric plants. According to the last official statistics (of 1911), there were in all Italy 46,194 motor power installations of a total horse-power of 1,620,404, of

which 977,906 were operated with electrical energy. The statistics show that there are 32,357 water-driven installations of a capacity of 951,836 H.P., of which 685,834 H.P. are converted into electric of 951,836 H.P., of which 685,834 H.P. are converted into electric power; 7.264 installations driven by steam power, with a capacity of 471,045 H.P., of which 224,506 H.P. are converted; 4,743 gaadriven installations of a total capacity of 167,501 H.P., of which 52,894 H.P. are converted; and 1,830 installations driven by either benzine, petrol or other substance, the total capacity being 30,024 H.P., of which 14,672 H.P. are converted into electric power.

Fatalities.—IRLAM.—An inquest was held at Irlam on March 17th, on Thos. John Roberts (33), who was jammed against a girder by an electric crane at the works of the Partington Steel and Iron Works. Peter McGowan, electric crane driver, said he was employed at the works, and was 15 years of age.—The Coroner: You are rather young to have charge of an electric crane.—Mr. Dobson (secretary): Not for this class of crane.—Mr. Ireland, H.M. Inspector of Factories, said the Board of Trade regulations stipulated 18 years of age.—Witness, continuing, said he was working the crane, and, from where he stood, could not see anyone near the girder. It appeared from further evidence that deceased was fastening a ladder to a girder, and no warning had been given, either to the crane-driver or to the men at the bottom of the ladder.—A verdict of "Accidental death" was returned, and Mr. Loxley, assistant engineer, said that in future he would have cranes stopped while repairs were in progress on the gantry.

MANCHESTER.—A verdict of "Accidental death," due to electric shock, was given by a Manchester Coroner's jury, on Friday last, after investigating the circumstances of the death (which took place the previous day) of Edward Sidney Wigglesworth (19), an apprenticed electrician to the British Westinghouse Co., Ltd., at Trafford Park. Deceased had been employed in the works for four years, and in the testing-room for about six months. Another Fatalities.—IRLAM.—An inquest was held at Irlam on

Trafford Park. Deceased had been employed in the works for your years, and in the testing-room for about six months. Another electrician, who was with him, said that on looking round he saw Wigglesworth in a state of collapse. He was apparently holding a live wire attached to the transformer; the voltage would be about 440.

Mr. Fraser, assistant superintendent of the electrical department, and that the cables were so insulated that they could be safely handled, provided a man kept clear of the obviously bare metal. The floor was also an insulator. On behalf of the company, Dr. Eastham, barrister, expressed regret at the accident, and sympathy with the relatives of the deceased.

#### OUR PERSONAL COLUMN.

The Editors invite electrical engineers, whether connected with the technical or the commercial side of the profession and industry, also electric tramway and railway officials, to keep readers of the ELECTRICAL REVIEW posted as to their movements.

Central Station Officials.—On relinquishing the post of station superintendent at the Battersea electricity works, to take up the position of generating engineer at the Reading Electricity Supply Co.'s works, Mr. ALEXANDER WHITIE was presented by the staff with a silver mounted crystal salad bowl and servers. In the absence of the chief engineer, Mr. H. F. J. Thompson, the chief assistant engineer, made the presentation. Mr. Whitie was also presented with an easy-chair from the workmen, and several other amall presents from individual members of the staff.

The Rochdale Corporation Electricity Committee last week decided to give further extension of leave to Mr. C. CLAREMONT ATCHISON, the electricity works manager, who recently underwent an operation, and whose recovery, so far, has not been quite as satisfactory as was originally hoped.

The Hackney Borough Council has been recommended to place Mr. F. C. Grimwood, sales department foreman, on the staff of the Ceuncil, at a fixed salary of £130 per annum. station superintendent at the Battersea electricity works, to take up

the Council, at a fixed salary of £130 per annum.

MR. W. H. TUNNICLIFFE has resigned the position of engineerin-charge under the Morley Corporation and is taking up a post in

the Botherham Corporation Tramways Department. Tramway Officials. -MR. H. PILLING, manager and

engineer of the Accrington Corporation tramways, is one of the four selected candidates for the position of manager of the South-ampton tramways. The salary is £400 per annum. Mr. Pilling has been with the Accrington Corporation eight years.

General.—Congratulations to Mr. Duncan Watson upon his election last week to be an Alderman of the Borough of Marylebone. Alderman Dancan Watson, who is chairman of the Electricity Committee, first took his seat in the Council between

four and five years ago.

MR. JOHN McMILLAR, who has for 24 years been with the Electric Construction Co., at Bushbury, Wolverhampton, and has for 10 years had entire control of the switchgear department, is leaving. The staff and employes have presented him with a collection of plate.

MR. F. YOUNG, electrician to the municipal tramways at Dover,

has resigned.

The Highways Committee of the L.C.C. recommends that Mr. G. H. Hume be appointed chairman, and Mr. J. Prestige vice-chairman of that Committee.

MR. W. M. FURNISS has been appointed by the board of directors as manager of the Electric Construction Co.'s Works, Wolverhampton, in succession to the late Mr. William Bulloch. Mr. Furniss took up his duties as manager as from 17th inst.

Obituary.—Lieut.-Col. Geo. Hollingworth, who was well known in Lancashire engineering circles, and the head of the firm of Booth & Hollingworth, civil and consulting engineers, of Manchester, and also consulting engineer and part proprietor of the Bredbury Colliery Co., died at his residence, Brinnington Lodge, Stockport, on Tuesday, after a fortnight's illness. He was for some years connected with the Lancashire Territorials, from which he retired recently with the rank of lieutenant-colonel. Lieut.-Col. Hollingworth was about 60 years of age.

#### NEW COMPANIES REGISTERED.

Manley & Sandy (1915), Ltd. (139,678).—This company was registered on March 17th, with a capital of £1,000 in £1 shares, to take over the assets of Manley & Sandy, Ltd., in liquidation, to carry on the business of electrical and mechanical engineers and contractors, suppliers of electricity, manufacturers of and dealers in machinery, electric, magnetic galvanic and other apparatus, etc. The subscribers (with one share each) are: G. B. Dobb, 16-18, Knightrider Street, E.C., manufacturer; J. W. Manley, Woodbury, New Barnet, Herts., engineer; R. B. Dobb, 2, Stone Buildings, Lincoln's Inn. W.C., solicitor. Private company. The number of directors is not to be less than two or more than five; the first are G. B. Dobb, J. W. Manley and R. B. Dobb, Qualification £5. Renumeration (except J. W. Manley) £52 each per annum. Solicitors: White & Dobb, 2, Stone Buildings, Lincoln's Inn, W.C.

Lincoln's Inn, W.C.

Mid-Somerset Electric Supply Co., Ltd. (139,699).—This company was registered on March 19th, with a capital of £7,000 in £1 shares, to adopt agreements (1) with Christy Bros. & Co., Ltd., for construction of plant, and (2) with C. & J. Clark, Ltd., for supply of electricity in bulk, to take a transfer at cost price of a Provisional Order acquired in the name of Christy Bros. & Co., Ltd., and to carry on the business indicated by the title. The subscribers (with one share each) are: F. Christy, 53, Broomfield Road, Chelmstord, electrical engineer; H. B. Clark, Notherleigh, Street, Somerset, shoe manufacturer; J. B. Clark, Overleigh House, Street, Somerset, shoe manufacturer; J. Worland, The Orchard, Street, Somerset, shirt rug manufacturer; J. Pursey, 172, High Street, Street, Somerset, auctioneer; F. W. Voake, 98, High Street, Street, Somerset, hutcher; J. E. Ward, Rowling Green, Street, Somerset, mill manager. Minimum cash subscription, 2,000 shares. The number of directors is not to be less than three or more than even; the first are F. Christy, H. B. Clark, J. B. Clark, J. C. Morland, J. Lursey, F. W. Voake and J. E. Ward. Qualification, 50 shares. Remuneration as fixed by the company. Solicitors: Duffield & Son, Chelmsford.

Tungsten, Ltd. (139,665).—This company was registered on March 16th, with a capital of £30,000 in £1 shares, to carry on the business of extractors, producers, refiners and manufacturers of tungsten, dealers in wolfram and tungsten and their products, metal workers, electrical engineers, electric lamp makers, etc., and to adopt an agreement with the National Industrial Syndicate, Ltd., F. W. Warburton, W. W. Crawford, P. Richardson and S. Clarke. The purchase consideration is £20,000 in shares, to be allotted as to 10,000 to the National Industrial Syndicate, Ltd. (vendors), as to 5,000 to P. Richardson, and as to 5,000 to S. Clarke. The shares are to be allotted to P. Richardson, and as to 5,000 to S. Clarke. The shares are to be allotted to P. Richardson and S. Clarke by request of the vendors as consideration for services rendered and for underwriting. The subscribers (with one share each) are: A. W. Bellman, 336, Liverpool Road, Highbury, N., law clerk; R. W. Eades, 91, Shelley Avenue, Manor Park, Essex, clerk, Private company. The number of directors is not to be less than two or more than five; the first are P. Richardson, S. Clarke and F. W. Warburton Qualification, 250 shares. Remuneration, £200 each per annum and £100 extra for the chairman, with any further remuneration voted by the company. Solicitors: Kenneth Brown, Baker, Baker & Co., Lennox House, Norfolk Street, W.C.

Seear, Scott & Co., Ltd. (139,663).—This company was registered on March 16th, with a capital of £1,000 in £1 shares (750-7 per cent. pref.), to carry on the business of railway, motor, cycle, mechanical, electrical, experimental and general engineers and manufacturers, model-makers, etc. The subscribers (with one share each) are: E. C. Seear, 16-17, Devonshire Square, E.C., electrical engineer; J. Scott, 51a, St. Peter's Street, Croydon, engineer. Private company. The number of directors is to be two; the first are E. C. Seear and J. Scott (provisional directors). Solicitor: W. Drake, 45, Chancery Lane, W.C.

Drake, 45, Chancery Lane, W.C.

Newton Brothers (Derby), Ltd. (139,711).—This company was registered on March 20th, with a capital of £31,000 in £1 shares (1,000 employés), to take over the business carried on at Alfredon Road, Beardsall, and at Derby, as "Newton Brothers," to carry on the business of electrical and mechanical engineers, manufacturers and workers of and dealers in electricity, motive power and light, manufacturers of and dealers in electricity, motive power and light, manufacturers of and dealers in electric lighting and power plants, dynamos, motors, cranes, pumps, motor vehicles, telegraphs, telephones, phonographs, accumulators, lamps and other apparatus, fee nders, metal workers, tool makers, dealers in hardware, etc., and to accept a proposal in writing made by C. A. Newton, R. Newton and H. Newton. The subscribers (with one share each) are: C. A. Newton, Midland Hotel, Derby, electrical engineer: R. Newton, 31, Hartington Street, Derby, electrical engineer: Private company. The number of directors is not to be less than two or more than six; the first are C. A. Newton, R. Newton and H. Newton and H. Newton (all permanent), Qualification £50, Remuneration as fixed by the company. Secretary: E. A. Swindall. Registered office: 21, Market Place, Derby.

#### OFFICIAL RETURNS OF ELECTRICAL COMPANIES.

Electric Reduction Co., Ltd.—A memorandum of satisfaction in full on February 9th, 1915, of debentures dated June 25th, 1903, securing £2,000, has been filed.

Brilliant Arc Lamp & Engineering Co., Ltd.—Issue on February 27th, 1915, of £50 debentures, part of a series of which particulars have already been filed.

Flexible Wheels, Ltd.—Mortgage on book debts dated March 12th, 1915, to secure £280. Holders: A. Whiteley, 33, Reed Pond Walk, Gidea Park, and S. W. Woolner, Temple Chambers, E.C.

Carville Site & Power Co., Ltd.—Particulars of £140,000 debentures, created December 21st, 1914, and secured by trust deed dated February 26th, 1915, filed pursuant to Section 93 (3) of the Companies' (Consolidation) Act, 1908, the amount of the present issue being £10,000. Property charged: The company's undertaking and property, present and future, including uncalled capital and freehold land at Carville, Northumberland, Trustees: Phænix Assurance Co., Ltd., 19, Lombard Street, E.C.

County of Dorset Electric Supply Co., Ltd.—Particulars of £16,000 debentures, created by resolutions of February 24th and December 28th, 1914, filed pursuant to Section 93 (3) of the Companies' (Consolidation) Act, 1908, the amount of the present issue being £3,000. Property charged: The company's undertaking and property, present and future, including capital (if any). No trustees.

Cambridge Electric Supply Co., Ltd. (36,457).—Capital, £100,000 in £10 shares. Return dated March 10th, 1915. 9,909 shares taken up. £9 per share called up. £89,181 paid. Mortgages and charges: £41,000 (£30,000 debentures and £11,000 loan from bankers).

St. James' and Pall Mall Electric Light Co., Ltd. (26,015).

—Capital £300,000 in 20,000 pref. and 40,000 ord, shares of £5 each. Return dated March 2nd, 1915. All shares taken up. £5 per share called up on 20,000 pref. and 39,650 ord.; £298,250 paid; £1,750 considered as paid on 350 shares. Mortgages and charges: £150,000 31 per cent, debenture stock and £236,729 4 per cent, guaranteed debenture stock of the Central Electric Supply Co., Ltd., being half of the total loan capital.

India Rubber, Gutta Percha & Telegraph Works Co., Ltd. (1,122C).—Capital £812,000 in 50,000 ord., 25,000 pref., and 6,200 unissued shares of £10 each. Return dated January 5th, 1915. 50,000 ord and 25,000 pref. shares taken up; £750,000 paid. Mortgages and charges: £400,000.

Auckland Electric Tramways Co., Ltd. (61,199).—Capital £600,000 in £1 shares (150,000 prel.). Return dated November 5th, 1914. All shares taken up. £1 per share called up; £585,100 paid, £14,900 considered as paid. Mortgages and charges, £408,327.

Westminster Electric Supply Corporation, Ltd. (27,061).

—Capital £2,000,000 in £5 shares (200,000 ord. and 200,000 4½ per cent. cum. pref.). Return dated March 10th, 1915. 110,000 ord. and 110,000 pref. shares taken up. £5 per share called up; £1,100,000 paid. Mortgages and charges, £250,000.

#### CITY NOTES.

#### London United Tramways, Ltd.

THE directors report that the operation of the undertaking The directors report that the operation of the undertaking during 1914 resulted in gross receipts amounting to £327,871. After adding the balance brought forward from 1913, and deducting all expenses chargeable to revenue, including an appropriation of £12,500 to reserve for reconstruction and renewals, there remains £8,142. The dividend on the preference shares at the rate of one-half per cent. per annum (paid in July last) absorbed £6,250, leaving £1,892 to be carried forward. The traffic receipts amounted to £316,838, a decrease of £11.768 due to war conditions. Owing to the number forward. The traffic receipts amounted to £316,838, a decrease of £11,768 due to war conditions. Owing to the number of employés who, as Reservists, were recalled to the colours, it was found necessary to reduce the services, and further reduction had subsequently to be made owing to the enlistment of employés in the new armies. 381 men are serving with the Forces, equivalent to about 24 per cent. of the entire staff. During the year a considerable length of track has been reconstructed, and £29,439 has been charged to the reserve for reconstruction and renewals.

Annual meeting: March 26th.

Wemyss and District Tramways Co., Ltd.—Presiding at the annual meeting in Edinburgh, Mr. George Balfour said that the receipts for 1914 showed a decrease of about £1,000, due entirely to the effect of the war on the districts through which the company's lines run. Notwithstanding the reduction in gross receipts, the net balance carried to the net profit and loss accounts. receipts, the net balance carried to the net profit and loss account was £6,819, only £745 less than a year ago, owing to economies in operating and general reduction in expenses. Taking all the circumstances into consideration, he thought the shareholders were to be congratulated on the result. During the year the doubling of the track, with a view to expediting the service from Leven to Kirkcaldy, was completed on a considerable portion of the system, and there was no doubt that this had materially improved the value of the property. value of the property.

South Metropolitan Electric Tramways and Lighting Co., Ltd.—The revenue for 1914 amounted to £65,324. The available balance is £16,721, and the directors propose to place £4,500 to reserve, against £5,000, to pay a dividend at the rate of 6 per cent. per annum on the preference shares for the year, 1913, and to pay on account of preference dividend for 1914 at the rate of 1 per cent. carrying forward £351 of 1 per cent., carrying forward £351.

Stock Exchange Notice. - The Committee has appointed Wednesday, April 14th, a special settling day in—
General Electric Co., Ltd.—Further issue of 10,000 ordinary shares of £10
each, fully paid, Nos. 40,001 to 50,000; and 30,000 6 per cent, cumulative preference shares of £10 each, fully paid, Nos. 40,001 to 70,000.

The preference shares mentioned are to be officially quoted.

Reduction of Capital .- TURNERS & MANVILLE, LTD., AND REDUCED.—A petition for confirming the reduction of the capital from £50,000 to £39,994 is to be heard on March 30th.

Robey & Co., Ltd.—Dividends of 4 per cent., free of income-tax, on the ordinary and preference shares for the year are recommended.

Winnipeg Electric Railway Co.—A dividend of 2½ per cent. for the quarter ending the 31st inst. is announced.

#### Metropolitan Electric Tramways, Ltd.

The revenue for 1914 amounted to £531,587. After adding the balance brought forward from 1913, and deducting all expenses chargeable to revenue, there remains an available balance of £47,605. There is to be placed to reserve account £12,000, dividend on the preference shares absorbs £25,000, dividend on the ordinary shares at the rate of 2 per cent. £9,487, and there is to be carried forward £1,118. £7,880 4½ per cent. debenture stock and £3,950 5 per cent. debenture stock has been bought and cancelled during the year. The traffic receipts amounted to £467,415, a decrease of £8,511 due to war conditions. Owing to the number of employes who, as Reservists, were recalled to the Colours, it was found necessary to reduce the services in August last. Further reducsary to reduce the services in August last. Further reductions had subsequently to be made owing to the enlistment of employes in the new armies. 484 employes, equivalent to about 25 per cent, of the total staff, are sorving in the Army or Navy.

The through running arrangements with the L.C.C. were extended in September last to the company's Great North Road route, through services being operated-from Barnet and North Finchley via Highgate to the Euston and Moorgate termini of the County Council's trainway system, and thereupon the annual payment of £2.300 made by the company to the L.C.C. in respect of the Archway Road trainway automatically ceased,

The County of Hertford Light Railways (Watford and Bushey Abandonment) Order, which was promoted by the Hertfordshire County Council in pursuance of the agreement with the company referred to in the last report, was confirmed by the Board of Trade in February last.

The business of the North Matropolitan Floatric Power

The business of the North Metropolitan Electric Power Supply Co., in spite of the decrease in the number of units supplied for traction purposes during the last five months of the year, has been satisfactorily maintained; the total number of units sold during 1914 amounted to 16,869,118, an increase of approximately 7 per cent. over the figures for the preceding year. Mr. George Richardson has resigned his seat on the board on account of ill-health. Mr. E. Garcke offers himself for re-election. for re-election.

Annual meeting: March 26th.

#### London and Suburban Traction Co., Ltd.

The revenue for 1914, consisting almost entirely of dividends and interest upon investments in and loans to the subsidiary companies, amounted to £118,580, as compared with £105,371. After deducting all expenses chargeable to revenue, including interest upon debenture stocks and loans and making provision for the sinking fund charges upon the 5 per cent. debenture stock, there remains £83,627, making, with £8,597 brought forward, £92,224 available for dividends. Out of this there has already been paid the full dividend on the 5 per cent. cum. pref. shares and an interim dividend at the rate of 1 per cent. per annum on the ordinary shares for the half-year ended June 30th last, leaving £2,886 to carry forward. In July last the directors felt justified, in view of the improving results then shown by the subsidiary companies, in declaring an interim dividend at the rate of 1 per cent. per annum upon the ordinary shares for the half-year ended June 30th last, and they had at that time no reason to believe that this rate of dividend could not be maintained for the whole and interest upon investments in and loans to the subsidiary this rate of dividend could not be maintained for the whole year. The war has had an adverse effect upon the tramway receipts, with the result that the revenue received by the comreceipts, with the result that the revenue received by the company for the year as a whole does not admit of the payment of any further dividend on the ordinary shares. In March last £350,000-5 per cent. "A" debenture stock, secured (inter alia) upon a like amount of unissued 4½ per cent, first mortgage debenture stock was created and sold. Additional shares in the Metropolitan Electric Tramways, Ltd., and the London United Tramways, Ltd., have been acquired in pursuance of the scheme of consolidation referred to in the last report, and the following capital of the company has been issued as fully paid:—£3,250 in 4½ per cent, first mort, deb. stock, £10,833 in 5 per cent, cum, pref. shares, £5,237 in ordinary shares.

#### Windsor Electrical Installation Co., Ltd.

THE capital expenditure during 1914 amounted to £933, bringing the total up to £94,166. The profit (including £408 brought forward) was £6,451, from which the following sums are deducted:—Debenture and other interest £701, dividend on 5 per cent, preference shares £1,086, depreciation, renewal and reserve fund £2,000, directors fees £350, leaving £2,314. and reserve fund £2,000, directors fees £350, leaving £2,314. Out of this a dividend of 4 per cent., less income tax, is recommended on the ordinary shares, and £465 is to be carried forward. The absence of the Court from Windsor, and the precautionary measures taken by the Home Office in restricting the lighting in the area, have adversely affected the revenue. During the year new lamps were connected equivalent to £577 of \$50.00, making the total 56,603 lamps. The board regret the death of their colleague, Mr. Edward Riley, but they do not propose to fill the vacancy.

#### Slough and Datchet Electric Supply Co., Ltd.

The capital expenditure during 1914 was £2,727, bringing the total up to £67,073. The new expenditure chiefly represents the provision of a new feeder cable from the works to Slough, to meet the growing demand for electricity. The equivalent of 1,227 additional lamps of Sc.P. have been connected.

	Lamps and motors									
Year.						connected.	Units sold.	Revenue.		
1912			• • •	•••		25,914	819,733 .	£.8,546		
1913				•		27,630	842,389 .	£5,900		
1914						28,857	831,803	£ 8,956		

The revenue would have shown a considerable increase but reference would have shown a considerable increase but for the war regulations put into force by the Government restricting the lighting over the whole area. The total net profit available for distribution is £4,830. £1,330 is to be allocated to depreciation and reserve, bringing it up to £8,620, and a dividend of 5 per cent. per annum, less income tax, is recommended, £427 being carried forward.

Altrincham Electric Supply, Ltd.-Mr. C. J. Ford, presiding at the annual meeting, held on 9th inst., said that they had spent £981 on new transformers, and that expenditure had had the effect of largely reducing the quantity of current unaccounted for, which was now 18 per cent. of the total generated, against 47 per cent. in 1910. When the remainder of the old transformers were renewed, there would be a still larger saving. A satisfactory increase in the demand for power might be expected in the near future; but for the insufficiency of labour preventing night work, the demand from such of the factories would have been larger. Lighting loads were affected by householders economies. Last year they spent £5,300 on capital account, and this year they would have to spend £7,000, mainly for new generating plant. The sole reason for their applying for a new prov. order was to enable them to remodel the capital of the company, as that could not be achieved by any other means. The report was adopted.

Minehead Electric Sunnly Co. Ltd.—The directors presiding at the annual meeting, held on 9th inst., said that they

Minchead Electric Supply Co., Ltd.—The directors report that in spite of the fact that the season in Minehead was very adversely affected by the war, a further expansion of business occurred during 1914, the total units sold amounting to 224,626, as compared with 212,969 for the previous year. Certain economies in working have been effected—the works costs now standing at the low figure of '79d, per unit sold—an exceptionally low cost for station of this give. During the wear the plant has been well a station of this size. During the year the plant has been well maintained and a number of new consumers have been connected. maintained and a number of new consumers have been connected. The profit on trading, after payment of interest on debentures &c. amounts to £1,967, plus £21 brought forward, less income-tax £63 and a year's dividend on the preference shares £450, leaving £1,475. A dividend of 8½ per cent. per annum on the ordinary shares (less tax) requires £216; bonuses to managing director and manager and secretary £115; there is to be put to depreciation and reserve fund (making same into £1,000) £1,000; leaving to carry forward £145. The directors record the death of Mr. E. Culverforward \$145. The directors record the death of Mr. E. Culverwell, a director.

Carmarthen Electric Supply Co., Ltd.—Mr. W. A. Schultz presided at the annual meeting held recently. The report submitted showed a profit of £1,293, after providing for all working charges. A dividend of 5 per cent. for the year on the ordinary shares was recommended. The consumers numbered 444, as compared with 374 in 1913 and they were still increasing. The chairpared with 374 in 1913, and they were still increasing. The chairman said that the company was in a thoroughly satisfactory position, and though they would be justified in raising the price of position, and though they would be justified in raising the price of electricity, they would not do so unless they were compelled. Mr. Blagdon Richards, who seconded, complimented the manager (Mr. H. Arthur), and said that if perchance they lost the public lighting, they would still be able to pay the same dividends as in the past. Sixteen new consumers had been secured since the beginning of the year. They had come to the end of necessary capital expenditure.

Barton Electric Light Supply Co., Ltd.—The annual meeting was held recently, and Mr. F. Hopper, the chairman, referred to the satisfactory profit of the year. The number of consumers had increased by over 60 per cent., and there was every prospect of a continuance of such increase. There was an unabated demand for light and power, and with the attention to detail which the directors were giving, there was an excellent prospect that given ordinary conditions the accounts would show better and better each year in the future. Mr. L. Collison, in seconding, pointed out that the capital of the company compared most favourably with that of other companies in similar places. most favourably with that of other companies in similar places. He felt sure that the shareholders would very soon look upon their holdings as a safe, remunerative and appreciating investment.

Liverpool District Lighting Co., Ltd.—During 1914 there was satisfactory progress, 5,733 lamps having been connected. steam engine and dynamo, in use since May last, have materially assisted in producing the extra profits. The directors do not anticipate any serious expenditure on capital account this year. After paying 4 per cent. for the year, £728 is to be carried forward.

Arbroath Electric Light and Power Co., Ltd.annual report shows a profit for the year amounting to £1,499. The balance in hand amounts to £1,037, which is to be carried forward to next year. The number of consumers is steadily increasing

#### Urban Electric Supply Co., Ltd.

The gross profits for 1914 amount to £68,962, as compared with £61,895 a year ago, and after deducting the expenses shown in the profit and loss account, a balance of £65,666 is shown in the profit and loss account, a balance of £65,666 is carried down to net profit and loss account. In the latter account the amounts required for interest and debenture stock redemption absorb £43,283, leaving an available balance, including £1,021 brought forward, of £23,404, which the directors recommend should be applied as follows:—To dividend of 5 per cent. for the year on the preference shares £12,500, to reserve for depreciation £10,904. The following table shows profits and the equivalent in 33 watt lamps connected at 31st December of each year:—

For the previous year the available balance was £23,021 out of which £12,000 was put to reserve for depreciation, 4 per cent, on the preference shares absorbed £10,000, and £1,021 was carried forward. The balance of the 5 per cent, dividend was then satisfied by funded dividend certificates.

Annual meeting: March 31st.

#### W. T. Henley's Telegraph Works, Ltd.

MR. SYDNEY GEDGE presided on Friday at the annual meeting held at the offices, 13 and 14, Blomfield Street, E.C. He first referred to the death of Mr. F. Newton, at the age of 80, who up till last year had been a director of the company since its commencement. The directors had made their annual visit to the works at Greenwich and Gravesend, and every visit only showed what great improvements were being made. By extensions and rearrangement their Greenwich works were becoming as convenient as the area of the site would allow. At Gravesend they had a fine area and were gradually using up that area by erecting works for the carrying on of the growing business of the company. They had to a certain extent suffered a loss of business by the war in two ways. extent suffered a loss of business by the war in two ways. First, many of those who supported golf and bought the company's balls were fighting at the front, with the result that the orders for golf balls had almost entirely ceased. They had, however, been able to employ the women engaged on their manufacture on other things in the works. Otherwise it might be said that the effect of the war on their trade had not been very great. No doubt they had lost some orders, but, on the whole, the orders they obtained from the Government on account of the war perhaps rather more than compensated them for other losses. Of course, these orders caused great anxiety, but he hoped it would never be said that Henley's works turned out anything which was not as perfectly made as it was possible to make it. When they came to manufacture that was a different thing. Manufacture had become more difficult and expensive. They had had higher to manufacture that was a different thing. Manufacture had become more difficult and expensive. They had had higher prices and increased wages, and also what, perhaps, ought to be mentioned first, the loss of men going to the Army. They regretted this and rejoiced at it. They rejoiced that out of their staff 333 men had gone to the front and they had only heard of three deaths so far. They had suffered in respect of these men going, but it had not prevented them going on with certain necessary extensions, although owing to the high prices they were following the old motto and making haste by going slowly. While they were endeavouring to keep pace with their actual wants, they were not doing more than was really necessary at the present time whilst the high prices remained. As to the accounts, there was an increase in every important item. The trade profits were £6,000 or £7,000, which was a few thousand more than the year before. other day he took out the figures for the last ten years and divided them in three-year periods, and found that in each succeeding three years there had been a steady increase. In each year they had been able to pay the same or greater dividends and put an increasing sum to reserve, with the result that they had a reserve account of no less than £215,000, whilst to that they were adding £20,000 this year, making a reserve account of £235,000, which on an ordinary capital of £200,000 might be considered to be most satisfactory. With regard to their investments in considered to their trustee. with regard to their investments in consols and other trustee securities, last year they reserved £15,603 against that sum, and thus these investments, which cost them £97,097, stood at £81,493. They did not think it necessary to reserve anything more this year against these securities. With regard to the profit and loss account, they had put by for depreciation of machinery £16,700, which was rather more than last

year, and they were able to carry to the general account £90,125, which was about £400 or £500 less than last year, and they were able to pay a dividend of 15 per cent. and a bonus of 5 per cent. Some of them would regret that they were not declaring the dividend free of income tax, but they were not declaring the dividend free of income tax, but they thought it better to make the change now than wait until the tax was increased, as it was bound to be. The Chairman next referred to the provision made for the dependents of the men who had joined the colours. At present it was costing them £3,000 a year, but it might be heavier, and they had set aside a special reserve of £10,000. When the war was over if it was not used it could then be dealt with. He was assured by the managers of the works that during the year the work had been done well, quietly and contentedly. They had been going into the question of the rise in the cost of living, and had made an arrangement with which he believed the workmen would be satisfied. They had also been considering the establishment of a pension scheme, but that had been postponed in consequence of the war. In conclusion, the Chairman dealt at length with the war and gave his reasons for

poned in consequence of the war. In conclusion, the Chairman dealt at length with the war and gave his reasons for believing that it would last at least another year.

Mr. G. Sutton (Managing Director), in seconding the motion, said that 1913 was the best trading year in the company's history, and at the last meeting he told them that they went forward with the promise that in 1914 the results would exceed the year 1913. They had reason for thinking so, for they had several large contracts on their books at that time the market prices for raw materials were steady and for they had several large contracts on their books at that time, the market prices for raw materials were steady, and the trade of the country generally was good. They had made a reputation for golf balls which had resulted in a considerable industry outside electric cables. When it came to the war all these things were upset. The large contracts were partially closed down; they had to go slowly at the request of their customers; market prices were anyhow; and it became a difficulty to get materials at all. The golf ball trade collapsed, although they made a good profit on their spring trade. But, notwithstanding all this, the profits of the company were greater than in the previous year and, what was perhaps even more satisfactory, the turnover of the company had been larger in 1914 than it had ever been before. But neither the turnover nor the profits had been increased by war material. They supplied large quantities of goods for the Admiralty and the War Department, and orders had been more numerous during the five months ending December than was usual, but the ordinary work which had been displaced was greater than the amount of work they had done for the Government. He wanted to make it quite clear that than was usual, but the ordinary work which had been displaced was greater than the amount of work they had done for the Government. He wanted to make it quite clear that they were not making large profits out of war materials and that the incidence of the war had put back their profit. What 1915 was going to be he could not say. They were busy with war material, but the work done for the War Department necessitated new machinery. The War Department had bought practically nothing from them since the Boer war, and now to supply the department they had to install new machinery. At the end of the war that machinery could only be partially employed, and the cost of it would go to swell the depreciation they would have to write off. So far as the Admiralty was concerned that did not apply, for they had always done work for them; but there again it had to be remembered that by the extraordinary pressure being put on them to turn out work quickly, the future, to a certain extent, was being mortgaged. The shareholders might ask why they did not charge prices which would cover the eventuality of scrapping the machinery. Rightly or wrongly, that was not the view the management took of their responsibility with regard to supplying the Government. They took the risk of how much use the machinery was going to be put to. The war might last six months or six years, and if it lasted for six years the machinery would be employed during the period and written off by depreciation. Therefore, the loss on depreciation would be greater according to the shortness of the war. He might tell them that at the outbreak of the war they wrote to the Admiralty and placed at their disposal for anything they might require, and said that with they wrote to the Admiralty and placed at their disposal the works of the company. They placed the works at their disposal for anything they might require, and said that with regard to payment they were prepared to leave the percentage of profit entirely to the Government Department. They, therefore, could not be put amongst those contractors who were said to be making a large sum of money from the country. With regard to the £10,000 special reserve which the Chairman had referred to, he could see that the cost to the company would be more than £10,000, for the bonus which had been given to the workpeople in consequence of the rise in the cost of food would cost them £8,000 or £9,000 a year. Their ordinary foreign business had grown owing to the war, Their ordinary foreign business had grown owing to the war. Their ordinary foreign business had grown owing to the war, and they were doing a great deal of work which used to be done in Germany. Although they were doing this work, the Government would not allow them to transport the work to its destination so freely as he thought they ought to. They had no difficulty in regard to some countries, but in the case of Holland they had great difficulty. They had shipments for Holland which had been waiting for two months, and pulces by next week they got permission to send them they unless by next week they got permission to send them they would have to stop doing trade with Holland, because it was not policy to manufacture special lines of goods and keep them in stock. He was not complaining of the action of the Government, for perhaps they knew better than he did, but he did know that none of their goods were going to an enemy country. They had spent a large sum of money in the exten-

sion of their works, and the shareholders were getting it back sion of their works, and the shareholders were getting it back in the way of increased profits. They had now double the number of buildings that they had originally at Gravesend. They were now spending £5,000 in building a large dining-hall for their workpeople there, and it would show no return except that return, which they could not estimate, from the comfort to their workpeople. They were making a large extension of the tyre factory. That branch was only started commercially in October, 1913, and within six months they decided to extend the buildings, which increased the output 200 per cent. Certainly their tyre business had been very successful. The good fortune which had followed the comsuccessful. The good fortune which had followed the company in electrical work was following it in this department of motor tyre construction. They had now passed plans for a further extension of the tyre factory which would enable them to make solid tyres for commercial vehicles. So far as they could judge from the two or three months which had allowed the correct very extensive to the two trees to the had. elapsed, the current year ought to be a good one. They had on hand several of the large contracts he had spoken of, and with good progress with the war they hoped they would be with good progress with the war they hoped they would be allowed to proceed at a normal rate with those contracts, and they would help to swell the profits for 1915. The actual business which was being carried from 1914 to 1915 was larger than he had ever known it. If they were to execute the orders on the books and did not take another order this year they could pay the shareholders a dividend at the end of the year. He did not think they could have anything more satisfactory than that as regarded the state of the business.

satisfactory than that as regarded the state of the business. The resolution was passed without discussion.

Mr. Drysdale proposed a vote of thanks to the board and the staff, and remarked that Mr. Sutton always modestly refrained from using the personal pronoun "I." It was always a case of "we" with him, and he (the speaker) did not think he took enough credit to himself.

Major Monsell seconded the motion and it was carried.

#### British Electric Transformer Co., Ltd.

Mr. A. F. Berry took the chair at Salisbury House, E.C., on Friday at the annual meeting. Before commencing the ordinary business, the Charkman alluded feelingly to the loss sustained by the company by the death of Mr. J. F. Albright, the late chairman, and the shareholders signified their concurrence in a vote of condolence with the family by standing in silence. In moving the adoption of the report the Charkman said sundry creditors were increased by 42.000 but in in silence. In moving the adoption of the report the CHARR-MAN said sundry creditors were increased by £2,900, but in view of the stock they had this was not a large figure. They had followed their usual practice of paying up promptly and obtaining all the cash discounts possible, but in order to do this they had had to borrow £6,000 from the bank. Depreciation reserve had been increased by £1,500, and they were suggesting the transference of a further £1,500 this year, which would bring up the total to £10,800. They also recommended adding another £5,000 to the reserve bringing the mended adding another £5,000 to the reserve, bringing the total up to £31,823. They would probably remember that this reserve was intended in the first instance as a reserve against their investments, some of which had considerably against their investments, some of which had consideranly depreciated in value. During the year one of the companies in which they held an interest went into liquidation, and they had written the asset out of the books and deducted it from the reserve account. With regard to the credit side of the balance sheet, they had allowed certain Continental patents to lapse. Their useful purpose had been served, and coving to the war they felt it was the right thing to do. The owing to the war they felt it was the right thing to do. The difference between the cost of these patents and the cost of new patents taken out had been deducted from the figure at new patents taken out had been deducted from the figure at which patents and goodwill stood, and left that item at £61,579 as against £65,054 last year. The investments stood at £2,655 and were now practically of that value, so that the whole of their reserve account of £31,831 could if necessary be set against this item of patents and goodwill. The addition of £1,018 to freehold land, plant, etc., was principally due to the plant and machinery purchased for the equipment of the last bay erected at Hayes, and had been necessary to cope with the additional business they had been doing. Stock and materials showed an increase of £23,000 and stood Stock and materials showed an increase of £23,000 and stood at £63,553. The increase was nearly all due to the railway and other contracts held up by reason of the outbreak of war, and since the end of the year the figure had been much reduced. Sundry debtors were about £9,000 more than last year and were all considered good. Up to that morning £23,000 had been received of the £45,638 standing in the accounts. The payment of the ordinary dividend was very carefully considered by the board, and, having regard to all the significant of 71 and the circumstances, they recommended a dividend of 73 per cent. It was with regret that they departed from the 10 per cent. It was with regret that they departed from the 10 per cent, they had paid for the last three years, but in view of the dislocation of trade and the fact that they thought it prudent to carry forward £3,477, he thought shareholders would agree that 71 per cent, was a good dividend. The Chairman explained at considerable length the reasons for the decrease of profit. In the first place the business felt the shock that civilisation as a whole felt at the outbreak of war. Then although the suppliers of material had done their best to assist them, yet the congestion of work which had occurred had affected the economical working of the factory. Then 80 per cent, of their men between 18 and 38 had joined the forces, and this made it extremely hard for those left to carry

on the work. It was imperative that the works at Hayes on the work. It was imperative that the works at Hayes should be kept going, for their machines were being largely used in the execution of Government contracts. They had trained and were training men to take the places of those who had left them, but, of course, it meant loss which could not be avoided. He had no doubt that the cost of educating these new men would come back to them in future years, but during 1914 it meant a reduction in output, and the profit was quite seriously affected. They had also had to set other but during 1914 it meant a reduction in output, and the profit was quite seriously affected. They had also had to set other work aside for Government work, and this was not conducive to economical manufacture. In August, September and October the works were badly upset by these and other causes, but in the last two months of the years things became more normal, although they were not now normal. Although there was a considerable difference this year, he was of opinion that the bulk of the difference in profit between last year and the previous year's working would be made up in the present and future years. As to the future, in the first place it might be assumed that immediately after the war the engineering section would be the busiest in the world. There would be repairs to the damaged districts and also the There would be repairs to the damaged districts and also the shifting of the centres of industry due to changes of the map. They would find that greatly increased activity prevailed in England after the war of 1870, and he thought it would take more than five years to repair the damage which was now being done. In this connection they had particularly to remember their clearing energy was appeared ing all other more than five years to repair the damage which was now being done. In this connection they had particularly to remember that electrical energy was superseding all other forms in domestic and industrial life. There was a natural tendency for factories to put in more and more electrical machinery; and, then, the trade which should be taken from German hands, not only in this country, but in the Colonies and abroad, ought to put a bigger strain on the producing people of this island. All these things seemed to indicate that they would find their productive powers taxed very heavily for many years to come in spite of the fact that dear money at the end of the war would possibly curtail the spending powers of certain countries with whom they did a good deal of trade. As to the situation at present, they had more unexecuted orders on hand than ever before. During January and February, and up to date in March, the orders they had received exceeded those for the corresponding period of last year by something over 50 per cent. The new men were rapidly gaining somewhat of the efficiency of the men they had lost, and they might reasonably look forward next year to a resumption of results more akin to those of the previous year than the last. They hoped one result of the war would be to increase the number of orders they received from the year than the last. They hoped one result of the war would be to increase the number of orders they received from the Colonies; already that was the case, although this was a business which, for financial reasons, one had to proceed with cautiously. In spite of the war their Tricity cooker business for 1914 compared favourably with 1913, and some 30 equipments had been ordered from them for warships. Electricity House also, in which they had an interest, was doing more business this year than last.

Mr. T. Rowe seconded the motion and the report was adonted.

adopted.

#### Brush Electrical Engineering Co., Ltd.

THE directors in their report for the year ended 31st December, 1914, state that effect has been given in the balance sheet to the reduction of capital. The conversion of the preference the reduction of capital. The conversion of the preference and ordinary shares forming the issued share capital of the company into ordinary stock has also been carried out. Notwithstanding the abnormal conditions prevailing during the second half of the year, the improvement in the company's position has been well maintained. A temporary effect of the position has been well maintained. A temporary effect of the outbreak of war was to cause a diminution in the volume of business, but the position in this respect has gradually improved, and the orders secured since the beginning of this year are above the average. The profit and loss account shows that after providing for general charges, maintenance of plant and buildings, and interest on the company's debanture tests. and buildings, and interest on the company's debenture stocks, there remains a balance of £19,110. The directors recommend that £10,000 be placed to a reserve account for depreciation, that £2,044 be applied in payment of the further 4 per cent. to which the holders of the company's 6 per cent. prior lien participating second debenture stock are entitled out of the first net profits available for dividend in any year; and that £7,065 be carried forward. Continued experience with the Lignostrom steam turbing has fully confirmed the and that £7,065 be carried forward. Continued experience with the Liungstrom steam turbine has fully confirmed the merits of this invention, and has proved its reliability under service conditions. The directors are of opinion that the present and prospective demand for this type of turbine present and prospective demand for this type of turbine justifies the capital expenditure necessary for its more economical production on a larger scale, and machine tools of modern and improved designs are on order for this purpose. The company is engaged on important contracts for the Admiralty and War Office Departments of H.M. Government, including the manufacture of aerollanes. To meet the outlay necessary for these various developments, and also to improve the company's manufacturing equipment in other departments, the directors propose (subject to the consent of the Treasury) to issue, when required, the balance of the 6 per cent, prior lien participating second debenture stock. On the outbreak of the war Mr. G. F. M. Cornwallis-West was recalled to the colours and he has since retired from the board. Annual meeting: March 29th.

#### Windermere and District Electric Supply Co., Ltd.

In their report for 1914, after expressing regret at the death of Mr. W. Long, a director, the board say that the gross revenue shows some expansion. This would have been distinctly greater but for the effect of the war, which seriously lessened the consumption, especially during August and September

The cable to Grasmere was completed in the spring of last year and a fair number of new consumers has been secured in that district. During the year 59 new consumers have been connected to the mains, constituting a record, and in addition numerous extensions have been made to other installations, including supplies for heating, cooking and power purposes. The sales of current show an increase of £165, and the total increase in gross revenue is £255. It is very unfortunate that the Diesel oil plant was not completed in contract time and is still not in service owing to defects which would in all probability have been remedied months ago but for the impossibility of the contractors obtaining the necessary material, the makers of which are fully engaged on Government orders. This delay is the more regrettable as it has entailed a very large increase in the cost of fuel for the year.

A payment of 5 per cent, on account of arrears of interest has been received on the Keswick Electric Light Co.'s debentures and the net revenue account has been reclited with £441 accordingly.

£3.200 of 5 per cent, debenture stock has been issued, being the balance of £20.000 authorised. The amount spent on capital account for new mains, transformers and meters has been £2.086.

The expenditure on revenue account for the year was £2,561, an increase of £361. The balance of revenue account is £1,613, plus £441 interest on Keswick debentures, and £3 brought forward. Out of this have been paid debenture interest, bankers' charges, etc., £955, interin dividend of 1 per cent. on preference shares £250, written off free wiring installations £75, transferred to depreciation reserve account £400, leaving £377. The directors recommend a further dividend of 1 per cent. (making 2 per cent. for the year) on the preference shares, leaving £127 to be carried forward.

#### Newcastle-on-Tyne Electric Supply Co., Ltd.

THE annual meeting was held in Newcastle on 16th inst. Mr J. H. Armstrong (vice-chairman), who presided, expressed regret that Dr. J. T. Merz, the chairman of the company, who since the beginning of February had been seriously ill, was unable to be present. Dr. Merz was still confined to his room, but was better. The H.P. connections to the system at the end of the year amounted to 231,425, an increase of 27,755, as compared with an increase of 29,341 H.P. in the previous year. The profits amounted to £184,969, a sum considerably more than in the preceding year, but these profits included year. The profits amounted to £184,969, a sum considerably more than in the preceding year, but these profits included the dividend on practically the whole of the shares in the Durham Co., which now belonged to the Newcastle Co. The interest charged on debenture stocks, loans, etc., amounted to £52,563, as against £42,632 in the previous year, but in the former figure there was the full interest charged on the recent issue of second debentures, which were created in October, 1913. The dividends were naturally larger than in the previous year, because the amount included the shares that had been given to the shareholders in the Durham Co. the previous year, because the amount included the shares that had been given to the shareholders in the Durham Co, under the fusion scheme, by which the Newcastle Co. acquired their rights. The transfer to depreciation account had been increased by £5,000, and the reserve fund had been increased from £10,000 to £17,000; £7,000 of the latter was a provision against possible losses on investments. During the past year they had spent £74,500 out of revenue upon the upkeep of plant, which included the cost of laying new services and mains, which many companies charged to capital account. They had kept the plant in thorough-going order, and this was illustrated by the fact that during the last six months a load had been thrown upon it at a moment's notice, which was mustrated by the fact that during the last six months a load had been thrown upon it at a moment's notice, which he felt sure it would never have carried had not the plant been in the highest state of efficiency. The total expenditure for the year had been £129,590, the greater part of which sum had been spent on the Dunston and Carville Stations, and £51,000 had been spent on the laying of mains. The increase of £6000 in management expenses was brought about crease of £6,000 in management expenses was brought about by two main items. The first was the expenses in connection by two main items. The first was the expenses in connection with the acquisition of the Durham shares and the sub-division of the Newcastle Company's shares to £1 shares, which amounted to £3,300, and the second item was the replacing of thirteen motor cars. These were not in a way management expenses, but their difficulty was that they had not a heading under which to place these items. Generally, the results of the revenue account were satisfactory, especially when they bore in mind that for five months of the year they had been working under what might be called the influences of war, and under most abnormal conditions. At the same time the profits had not come up to the expectations of the directors, purely because of the effects of the war. Fortunately the Northumberland area of the company did not suffer so much as the Durham area, as they had had certain counteracting influences in the shape of large demands made upon them by local companies who were manufacturing for the Government war and other materials. The collieries had been working short time, but there was an unusual demand for current in war and other materials. The collieries had been working short time, but there was an unusual demand for current in other directions. Last year the company's programme of increased output included a 16,000 H.P. turbo-generator, due for delivery before the end of the year, but in consequence of the war there was delay in delivery. When the Government made an order for plant, it meant an order, and it had the first claim on the whole of their output. As the shareholders knew, the company had a very extensive system, and had various sources of supply in different parts of their area, and

by spending considerable sums on the rearrangement of their plant they had been able to successfully deal with all the de-mands made upon them. Their difficulties had been increased mands made upon them. Their dimensities had been increased by 11 per cent. of their employés, all skilled, having joined the services. They had to remember that their business was a continuous one, running the twenty-four hours, and they had to take a load so great as they had done when short of skilled men. They would appreciate the demands that had been made upon their staff, and, he thought, the thanks of the directors and the shareholders were due to the officials and the employés for the hearty manner in which they had faced and overcome difficulties. The positions of the employés who had enlisted had been safeguarded, and allowances to the wives and dependents made up their wages to what they were at the time of enlistment. The cost to the company in this respect was about £200 a month. The company might congratulate itself upon having got over a very difficult time, and upon solving difficult problems. The new plant was running in January, and during the last five months the company hot been of enormous benefit to the country. Had that company not been in existence the effect on the war would have been very serious. If the companies who were manufacturing for the Government had been dependent on their own private supplies, and if they had had to order plant to meet the requirements, they could not have got it for at least a year or more. As it was, the Newcastle Company was able to come and keep things going. He thought that the prospects for the coming year were satisfactory. In regard to the interim dividend he had a word to say. It might be that their works might be bombarded—they never could tell—and they might be stopped working altogether. He pointed out that when the directors paid an interim dividend on the ordinary shares they did so on their own responsibility. That was a risk that many directors in the country might decline to take. If the directors found it necessary not to pay an interim dividend this year it would not mean that the profits were not able to pay it, or that necessarily there by 11 per cent. of their employes, all skilled, having joined the services. They had to remember that their business was a shareholders as soon as the accounts were made up at the end

of the year.

Sir LINDSAY WOOD seconded the report, which was adopted. The dividends of 5 per cent. on the preference and 51 per cent. on the ordinary shares were declared. The directors were authorised to expend £1.000 (of which £200 had already been report) for various relief funds.

#### City of London Electric Lighting Co., Ltd.

MR. J. B. Braithwaite presided on March 16th over the annual meeting, held at Salisbury House, E.C. He said that there was no alteration in the capital account, nor, indeed, had there been for many years. He pointed out last year that they had provided £766,000 out of revenue for capital purposes, and this year that amount had been raised to £816,862. Assuming that they had had to raise that capital at 5 per cent. it would have involved them in an extra charge for interest of £41,000, which they had been saved by the liberal allocations it would have involved them in an extra charge for interest of £41,000, which they had been saved by the liberal allocations of £50,000 a year which they had made for the last ten years to depreciation. The capital expenditure for the year was rather heavier than for the last two or three years—£61,938 as against £49,436 for 1913, and £45,508 in 1912. The increase last year was due to the final payments for the most up-to-date turbine plant which they had recently installed in their power-house at Bankside. That installation had given them improved economy in their generating expenses. The expenditure on mains in the case of their company was not a heavy annual item. They had only one square mile to serve, and when they laid down the mains originally they allowed for a considerable increase of business, and therefore they were relieved of what to most electric lighting companies was one considerable increase of business, and therefore they were relieved of what to most electric lighting companies was one of the heaviest expenses. With regard to the revenue, they had had a great disappointment, for owing to the war, for the first time since 1910 the net revenue showed a shrinkage. At the end of June they had an increase in revenue of £2,000, but they finished the year £8,229 to the bad, so that the war had cost them £10,500 in reduced revenue. That was not to be wondered at because, before the war actually broke out the Stock Exchange was closed, and the whole of the members, some thousands in number, carried on business within the company's area. Therefore the entire closing of the Exchange for five months in itself had led to a considerable reduction in the demand for lighting. The general stagnation of business in the city had also helped to reduce their revenue, so that on the whole, when they considered what the amount of business in the city had also helped to reduce their revenue, so that on the whole, when they considered what the amount of their total revenue was, they might consider themselves fortunate to have escaped with an actual decrease of £10,500 gross. The decreased revenue had been accentuated to some extent, because they had had an increase of £1,897 in the working expenses, so that altogether, as compared with the previous year, they were £10,126 to the bad on the balance. The result was that they had had to go back one per cent, in the dividend, which accounted for £7,000, and the balance they had taken from the addition which they made last year to carry forward, leaving that figure at £23,400. As they knew, he regarded £20,000 as their proper carry forward, and knew, he regarded £20,000 as their proper carry forward, and anything above that was equal to a dividend equalisation account. Therefore they still had a margin of £3,400 available for any further reduction in profits that might occur this year. Their great difficulty at the present time was the dislocation

which the war had caused in the coal traffic. The Government had commandeered a great many of the vessels previously employed in conveying coal to London, and they had also taken over many of the railway wagons, with the result that coal had gone up very much in price. They were living from "hand to mouth," as it were, in regard to their coal supply at the present time, and they did not quite know what the effect would be during the current year. They proposed to invite their customers to share with them the burden which the difficulty of obtaining coal and its ephaned coat what the effect would be during the current year. They proposed to invite their customers to share with them the burden which the difficulty of obtaining coal and its enhanced cost were throwing upon the company. Those who had been using electric power had hitherto got off scot free whenever there had been coal difficulties or anything of that kind, and the shareholders had borne the whole of the burden. They felt, however, that the time had now come when they must ask their consumers to share part of the burden, and he did not believe that their customers would object for the time being to take their part. With regard to the heating output, that was steadily increasing, and now exceeded two million units, or an increase of 20 per cent. over 1913, so that it looked as if the 'advantages of electric heating were gradually being more and more appreciated. They had 5,403 kw. at the end of 1914 connected for heating purposes, an increase of 533 kw., being the largest increase they had ever had in any one year. The net increase in connections for all purposes during 1914 amounted to 1,829 kw., which he thought was as much as they could reasonably expect in view of the five months of the war period which the accounts covered. They would be glad to know that 87 of their permanent staff and workmen had joined the naval or military forces, and they were making suitable allowances to all such or their dependents, and keeping their places open as far as was possible. The Marquis of Winchester, one of their directors, was also away on active service. The absence of so many workers at the front had recessarily had joined the naval or military forces, and they were making suitable allowances to all such or their dependents, and keeping their places open as far as was possible. The Marquis of Winchester, one of their directors, was also away on active service. The absence of so many workers at the front had necessarily thrown a large amount of extra work upon those who had remained behind, and they could congratulate themselves on having a staff that was thoroughly loyal and willing to help its country wherever its help was most needed. They had thought it right to carry to a suspense account the special expenses incurred in connection with the war, and this year they had carried £1,318 to such account. He told them last year that they had come to an arrangement with the City Corporation as regarded public lighting, and had commenced the installation. Had it not been for the war, by this time they would have had the gratification of seeing those parts of the city which they had undertaken to light, the best lit thoroughfares of any great capital in Europe. Owing to the restrictions put upon the public lighting, the benefit of what they had done had not yet become apparent, but it would be seen when the war was over and normal lighting was resumed in the streets. He might say that February 18th last was the last day on which the Corporation could exercise their power of purchase. They had, however, allowed that unique opportunity to slip by, and had not given the necessary notice; therefore the shareholders might take it that the company would remain theirs for the rest of the term. Having referred at some length to the abortive attempts to introduce legislation for the unification of London's electric supply, Mr. Braithwaite concluded his remarks by saying that the directors would continue to do their best for the company during the current year, and he hoped that when he met the shareholders next year he might have a relatively good report to present. present.

Mr. F. W. REYNOLDS seconded the motion.

Mr. Deputy Millar Wilkinson, C.C., congratulated the directors upon the report, and said he was glad to think that the Corporation had not exercised their powers of purchase. It was quite possible that the Corporation was so imbued with the excellent management of the company that they felt that they could not possibly do any better for the citizens and therefore they had left the company alone. With regard to legislation, he was very glad that the L.C.C. had dropped its Bill.

to legislation, he was very giad that the L.C.C. had dropped its Bill.

The CHAIRMAN remarked that he, too, was glad that the L.C.C. Bill had been dropped, and although there was nothing to prevent them bringing forward a similar measure in the future, he rather fancied that the Council would be very chary of taking up the question again.

The report was adopted.

#### Direct Spanish Telegraph Co., Ltd.

Sir John Denison-Pender, K.C.M.G., presided on March 18th at the annual meeting, held at Electra House, E.C. He said that the traffic receipts showed an increased of £18,000. The ordinary working expenses had increased by £3,119—to £19,832. Salaries in London had increased by £439, which was chiefly accounted for by an improvement in the position of their head office staff granted by the board, and which therefore became more or less a permanent charge. A small portion of the increase was due to overtime necessitated by the absence of some of the staff in the army, and extra work at the head office owing to the increase of traffic over the whole system. Salaries at stations showed an increase of £2.258, due to several causes, the principal cause being a revision of the salary schemes at the stations. The increased work caused by the pressure of traffic had of course also contributed to that increased expenditure. They had contributed SIR JOHN DENISON-PENDER, K.C.M.G., presided on March 18th tributed to that increased expenditure. They had contributed £400 to War funds, they having joined with the associated

companies in sending donations to the Red Cross and other leading funds. The Bilbao cable broke down on September 23rd last three knots from the landing place in Cornwall, con-23rd last three knots from the landing place in Cornwall, connection being restored on September 27th. They were most fortunate in getting the services of the cable steamer Electra without any delay, and in having fine weather, with the result that the interruption only lasted five days. The cost of repairs was only £327, which had been charged against revenue. That was the only break they had had during 1914, and be thought perhaps it was the smartest repair and the cheapest that the company had ever had in the course of its existence. The £31 001 41 per cent first mortuges debentures and be thought perhaps it was the smartest repair and the cheapest that the company had ever had in the course of its existence. The £30,000 4½ per cent first mortgage debentures of the company matured and were paid off on June 30 last. Instead of realising securities from the reserve fund, which would have caused a considerable loss on their purchase value, the directors arranged with the Eastern Telegraph Co. to find the balance required to pay the debentures, they being given the opportunity of paying off any part of the advance as the money came in. That was a considerable advantage, and the sum of £10,000 outstanding at 31st December had since that date been further reduced, and now stood at only £2,000. With regard to the increased profit, as they knew, there were three direct routes to Spain—the British and French land lines via the Channel and Bordeaux; the Eastern Cables via Vigo; and the direct Spanish route via Bilbao. When the war broke out naturally the British and French lines became fully occupied by Government traffic, and that pressure was augmented during the short period the French Government removed from Paris to Bordeaux. The result was that a very large proportion of the land line traffic to and from Spain was transferred to the Direct Spanish and the Eastern Cables. Also the Direct Spanish Co. benefited materially by having a good route, though naturally at a higher price, to the South of France via the Bilbao cable land line across Spain, and the Bilbao-Marseilles cable to Marseilles, and the public took advantage of that route when the English and the French land line routes were congested. He could not, therefore, say whether the total volume of traffic with Spain had increased since the war started, or whether the increase was due to the pressure of Government traffic on lines which in times past carried their full share of work, and which were keen compressure of Government traffic on lines which in times past carried their full share of work, and which were keen competitors for Spanish traffic. The result of the year was that, after providing for interest to the 30th June, 1914, on the debentures, and the amount required to complete their redemption, providing for the depreciation on their securities. demption, providing for the depreciation on their securities as at the present date, and placing £5,000 to reserve, the directors recommended payment of a dividend at the rate of 10 percent, on the preference shares, and the usual dividend at the rate of 4 per cent, on the ordinary shares. In addition, they considered they were justified in recommending a bonus of 2s, per cent, on the ordinary shares, without weakening the financial position of the company, which it was their first duty to maintain. to maintain.

Sir Albert J. Leppoc Cappel seconded the motion, which was

carried

#### British L. M. Ericsson Manufacturing Co., Ltd.

The annual meeting was held on March 17th at the Memorial Hall, Farringdon Street, E.C. Mr. W. M. Crowe, who presided, said that the net profits amounted to £20,614, as against £23,808 in 1913, and £18,562 in 1912. It would be seen, therefore, that although the profits were somewhat smaller than in 1913 they were somewhat larger than in 1912. They might congratulate themselves on being able to show such a good result in face of the exceptional circumstances of last year and the difficulties of the latter part of the period. Those difficulties included, amongst other things, the supply of raw material, which was a very serious difficulty to a company such as theirs. That was brought about by the enormous demands by the Government for materials for war purposes, and the tact that suppliers gave preference to Government orders before theirs were considered, although they were working on Government contracts. gave preference to Government orders before theirs were considered, although they were working on Government contracts. Labour became scarce in consequence of the large number of men who left the factory to join the army, and they had great difficulty in replacing those men who were, for all practical purposes, specialists in their particular line of work. In the end they had to apply to the Government for protection against the recruiting officer, otherwise they could not possibly have kept anything like delivery time. Towards the end of January they received letters both from the War Office and the Post Office giving them the required protection, and pointing out to the men that they were serving the country in the factory as well as if they had been in the field, since they were helping with Government contracts in a time of emergency. Those letters helped them somewhat, but etil the men continued to go, and they could not but admire their enthusiasm, even although they suffered from it. Wages went up as a natural consequence of the labour demand being more than the supply, and that, along with the increased price of up as a natural consequence of the labour demand being more than the supply, and that, along with the increased price of materials, helped to reduce the profits, particularly on orders taken before the commencement of the war and before labour troubles began. Taking everything into consideration, he thought they might congratulate themselves upon such good results. He was glad to say that the factory was now full of work, and they could have secured orders for possibly double the amount if only they had had the capacity to deal with them. At the present time they were increasing the capacity of the At the present time they were increasing the capacity of the

works by putting in new plant and machinery. They were not providing specially for "passing" work brought about by the present state of affairs in the country, although the Government might come and tell them that they would have to use the plant for those purposes. They were providing for work which they trusted would remain in the country after the war had ceased and peace had been signed. That prospect of retaining in the country industries, which in the past had been in the hands of what were now enemy countries depended very largely on what action the Government might take in order to protect home industries. He thought the Government was beginning to see the necessity for this, and that they might have legislation on the point before very long—in any case, let them hope so. They at the present time were entering upon a new field of manufacture, which would require that protection if the particular article in question was to remain in this country as an industry—he meant the making of magnetos for motor-cars and motor-cycles, also for ing of magnetos for motor-cars and motor-cycles, also for motor accessories. In the past those things had been almost altogether made in Germany, and doubtless the Germans would, at the end of the war, do all that was possible to recover the trade, and they might be able to do it if the Government did not come to the support and protection of such companies as theirs, and many others throughout the country which had spent, and were spending, large sums of money in promoting new home industries. The business was an enormous one, as was shown by the immense factories in Germany, employing thousands of hands, engaged altogether in that class of work. The time was encerture for these to enter into employing thousands of hands, engaged altogether in that class of work. The time was opportune for them to enter into the business, and their factory was well suited to the purpose, and he hoped that by this time next year good results would be shown. The magneto on which they had pinned their faith was named the "B.E.C."—the initials of the company, and was the invention of Mr. W. C. Burling, the manager of the Ericsson Manufacturing Co., of Buffalo, U.S.A., which company was closely allied to theirs. Already they had orders for some thousands of them. With regard to the new Act just passed and Lord Kitchener's message to the manufacturers he could only say that their factory was already fully engaged on, Government work; and, therefore, they would probably be undisturbed. But if it should happen that they were required to put their full forces on the output of war material, then the Government would not find them wanting. He thought, however, they were doing their full share, seeing that there was very little else going through the factory than Government work. With regard to the financial strength of the company, it was sounder than even last year. They had written off liberally for depreciation—close on £11,000 last year, and during the past seven years they had written off £80,000. They had also gone very carefully into the stocks of material to see that no article was priced above its actual value, or where any article had become obsolete it was either written off altogether or greatly written down. There was nothing in the books for goodwill, patents, or anything of that kind—there was not a penny piece of doubtful assets in the company. Out of the net profits they recommended that £6,000 be nlaced to reserve, as against £5,000 last year, and that £7,023 be carried forward, as compared with £6,405 a year ago. He might remind them that the carry forward was £1,000 more than enough to pay the preference dividend this year if no profits were made. The prospects, however, were that 1915 would be an excellent class of work. The time was opportune for them to enter into the business, and their factory was well suited to the purpose,

was adopted.

#### Bath Electric Tramways, Ltd.

Bath Electric Tramways, Ltd.

The annual meeting was held on March 18th at Winchester House, E.C. Sir James Stvewright, K.C.M.G., who presided, said there was nothing to be ashamed of in the report or in the result of the operations of the company during what Mr. Hamilton described as "an extraordinary year for tramways." Mr. Hamilton, of the Leeds tramways, was the expert whom they called in to advise upon their system of management, and he was credited with being one of the best authorities in Great Britain upon tramways. He had made out the report which the shareholders had already seen, and which the board thought it right to get in view of the criticisms which had been passed on their management by a certain section of the shareholders. The board called Mr. Hamilton in as a Balaam to curse them, but instead of doing so he blessed them in his report, and so satisfied was he with the management and the future prospects of the company that he was now a fairly large shareholder. He would have been at the meeting, but had had to go to Edinburgh in connection with a tramway inquiry. He had written them a letter, in which he said: "I think there cannot be the faintest shadow of real criticism about any of the accounts of the company during the past extraordinary year." They would see from the report that the traffic and other receipts showed a decrease of £1,049 for the 52 weeks of 1914, compared with the 53 weeks of the previous year. On the other hand, however, the

expenses had only amounted to £16,132, as against £17,008; therefore, although the gross receipts were over £1,000 less, the net result was nothing nearly so bad. That was why he thought it was misleading for tramway companies to publish the net result was nothing nearly so bad. That was why he thought it was misleading for tramway companies to publish their weekly or monthly traffic receipts, as shareholders were apt to get unduly alarmed. Take their own case for the first two months of the present year. The total traffic receipts were only £5,025, as against £5,594 for the corresponding period of 1914, but looking to the net revenue they had made a profit this year of £1,113, against £1,266 during the corresponding period last year. Up to the outbreak of the war they were doing extremely well, and were far ahead in the revenue as compared with the same period in 1913, and if they had gone on at that rate, instead of being £1,000 behind, they would have shown quite that increase over 1913, which was a record service to the country by disposing of several of their motors to the Government. They lost nothing by the transaction, as the price they obtained for the vehicles was almost within a shilling of the price at which they stood in their books. They had also been able to do a good deal of work for the military on Salisbury Plain. That was not particularly profitable, but they were glad to render what service they could to the Government in this time of emergency. They had been put to considerable expense to dispose of the adverse criticisms of those who wished to get the management of the company into their own hands. Those gentlemen had ulterior motives which the board did not agree with, and they had been proved to be right. The savings which had been effected as a result of the recommendations of Mr. Hamilton had not been seen this year owing to the military work which the company had undertaken at practically no profit. The auditors drew attention to the fact that nothing had been written off for depreciation. He would, however, remind them that they had spent £25,000 on capital account, and they had intended floating more debentures to meet that charge, but the terms were so onerous that on capital account, and they had intended floating more deben-tures to meet that charge, but the terms were so onerous that they could not bring them before the shareholders. They had carried that loan at the bank and had made provision this year for £2,000 out of revenue to reduce the loan; and they were carrying forward £5,234 to the next account, and they intended to use that amount in replacing their motors. intended to use that amount in replacing their motors. With regard to the future, he was by no means despondent. As he had said, for the first two months of this year they were only £123 down as compared with last year, and he believed that if they had a fine spring and summer, although the war might still be raging, they had got a very fair future before them for the current year. Their foundry, which was very much criticised, was doing splendid work. It was said by some that they had made a bad bargain when they bought the foundry, but it was doing all their own work and other work as well, and was showing a very handsome return.

Mr. A. Campbell Swinton seconded the motion, which was adopted without discussion.

was adopted without discussion.

#### Brompton and Kensington Electricity Supply Co., Ltd.

THE annual meeting was held at the offices of the company, 254, Earl's Court Road, S.W., on March 18th. Mr. H. R. Beeton, who presided, said that the development of the business during the past year showed a remarkable similarity to that of the year before, although the conditions under which they had worked had been very different. Again they had to complain of a decrease of profit, notwithstanding a satisfactory growth in their connections, and again the benefit of more efficient plant had been offset by a further heavy increase in rates and taxes. The effects of the war on their revenue during the second half of the year was to cause them to lose much of the gain which they had secured during the first half of the year—due, of course, to a general disposition to economise in the national emergency, and to the police restrictions on lighting, which he trusted might soon be relaxed. Although they connected fewer customers, and although their customers consumed less current per lamp installed than during the previous year, the growth of electric cooking in the area resulted in their securing a larger number of lamp connections, so that they actually sold, in spite of the war, 112,000 more units in 1914 than in 1913. As, however, a larger proportion of the units sold were for purposes other than lighting, the average price received per unit was less, and the revenue barely equalled that of 1913. The more effi-THE annual meeting was held at the offices of the company, a larger proportion of the units sold were for purposes other than lighting, the average price received per unit was less, and the revenue barely equalled that of 1913. The more efficient plant which they substituted in 1913, and which they were extending this year, enabled them to produce a larger output with a smaller coal consumption, so that although the cost of coal was slightly higher they were enabled to further reduce their works cost, which, he was pleased to say, was now the lowest in their history. The most noteworthy feature of the accounts was that the decrease in net profit of £1,229, as compared with the preceding year, was more than accounted for by the increase of £1,430 in rates and taxes, attributable in part to an enhanced valuation for and taxes, attributable in part to an enhanced valuation for rating purposes. He ventured to think it was a somewhat striking commentary upon their system of local taxation that an enterprise like theirs, which contributed so largely to the public advantage and enhanced so greatly the value of property, should be burdened to the extent of about 20 per cent. of its expenditure for the purposes of local government. The directors had been unable to acquiesce in the view taken by the assessment committee that their undertaking, which earned

Digitized by GOGIC

£1,700 less in 1913 than in 1912, and £1,200 less in 1914 than in 1913, possessed a greater rateable value in those years, and they were appealing with confidence to Quarter Sessions for relief from the provisional assessment which the local authority has seen in to make. In the circumstances in which they found themselves to-day there was little doubt that the result of the working of the year on which they had now entered was likely to be even less satisfactory than that now under review, because although they were again substi-tuting more efficient plant at a capital sacrifice, which would result in further economy in working, they would not derive the benefit from such expenditure until the close of the year, and they would have to face considerably increased expenditure on coal and wages, due, in the latter case, to the payment of half wages to the dependents of their employés who had enlisted, and to a war grant which they had made payable monthly to those employés who remained, in order to assist them in meeting the temporarily increased cost of living. assist them in meeting the temporarily increased cost of living. In regard to the appropriation of the balance of net revenue, they were recommending that the company's investments be written down to their value at the close of the year, instead of at the close of the Stock Exchange, which involved a provision of £1,100, instead of £200, against possible loss on realisation, although the latter date had been more generally adopted by banks and other joint stock companies holding similar securities. They were also recommending the same provision to reserve find as last year, and the writing off £1,000. vision to reserve fund as last year, and the writing off of £1,000 more on shares in and advances to the Accessories Company. They hoped that this provision against loss on capital sunk in the course of founding this branch of the business might prove They hoped that this provision against loss on capital sunk in the course of founding this branch of the business might prove excessive, but the war had not only interfered with their manufacture and sales, but it had also disorganised their accountancy, and in face of delay in completing the final accounts it was well to give themselves the benefit of any doubt as to results. In view of the heavy increase in income tax they thought it was prudent to discontinue the payment of the dividend on the ordinary shares free, which for the ensuing year would represent a covert bonus of 12½ per cent. or a virtual dividend of 11½ per cent. Such a distribution of profits would enable them to pay their customary dividend of 10 per cent., which they had now paid regularly for the past thirteen years, and would enable them to carry forward a balance of £5,625 as against £7,152 last year, the total of their reserves and undivided profits amounting to £130,000, as against £125,000 twelve months ago. He was pleased to say that 35 out of a total of 165 men in the employment of the Supply and Accessories Companies had joined the colours. These would be reinstated at the close of the war, and in the meantime they were paying at the rate of £840 per annum to their dependents. This large drain on their establishment, which they deemed it right to encourage, had imposed a considerable burden on the staff which remained, a number of whom had been enrolled as special constables and were doing voluntary guard duty during the night at the company's generating and sub-stations. Thus both those who had gone and those who had stayed behind were discharging their public duty under trying circumstances, and the recognition of the shareholders was due to them accordingly. Whilst the and those who had stayed behind were discharging their public duty under trying circumstances, and the recognition of the shareholders was due to them accordingly. Whilst the disorganisation which the war had entailed upon them prevented him from entering as definitely into the results of the working of the Accessories business as he would like, he might say that the restaurant continued to make satisfactory progress in spite of the times, and that although the manufacturing department was practically depleted of men by enlistment and had difficulty in obtaining materials, it also had made and had difficulty in obtaining materials, it also had made considerable progress, and had completed designs for a great variety of apparatus suitable for public institutions, hotels, restaurants, clubs and private houses. They were installing large equipments in several of the most important cities in the country, and as they were confident that these would give the country, and as they were confident that these would give the same satisfaction in use as the domestic cookers installed in their own area, they might reasonably look forward, with a return to normal conditions, to the profitable development of this branch of the business, apart altogether from the advantage which inured incidentally to the company. The continually recurring endeavours at such vast, and so far, unavailing, expenditure of public and private money, to remedy the disadvantages and remove the difficulties which had been the outcome of the conditions imposed by Parliament, in its zeal to protect the public from the rapacity of had been the outcome of the conditions imposed by Parliament, in its zeal to protect the public from the rapacity of private enterprise, at the inception of their industry, were renewed with exemplary bravery in the past year, but only to meet with failure as usual. Both the County Council and the companies, with one or two regrettable exceptions, promoted bills for the better co-ordination and development of the supply of the Metropolis, and negotiations were entered upon between the parties to harmonise, if possible, their separate endeavours. But the innocents were both massacred, the one at the hands of the LCC, itself and the other at the hands of Parliament, and a solution was therefore still to seek. It was unnecessary to enter into the details which distinguished rariament, and a solution was therefore still to seek. It was unnecessary to enter into the details which distinguished those well-meant schemes from each other further than to say that the companies, who had certainly had more experience of the problem in hand, did not share the sanguine expectations of results likely to accrue from extreme concentration which were held out to the County Council by its professional expert advisers. It was, however, the intention of the companies to persevere in an endeavour to effect an amalgamation on fair terms which would safeguard the interests of mation on fair terms which would safeguard the interests of the shareholders as well as the public by removing the necessity under which the companies would come to labour, of restricting development so as to avoid loss by the operation of the existing purchase clause. In their endeavour to do that their directors would keep them advised of any definite steps which might be taken.

which might be taken.

Col. W. F. LEETE seconded the motion.

The report and accounts were adopted.

#### Bournemouth and Poole Electricity Supply Co., Ltd.

MR. J. A. Hosker (Vice-Chairman) presided on March 18th, at Moorgate Court, E.C., over the annual meeting. After expressing regret at the absence of Mr. Sanderson, the Chair-MAN said that at last year's meeting an optimistic view was taken of their prospects in the present and succeeding years. Since then the war had affected their business. It was, however, a source of keen satisfaction that they were able to submit the result of their working in the past year, which, although not quite equal to former anticipations, was eminently satisfactory. Their issue of the balance of the unissued second preference shares, viz., 2,500 of £10 each at par, though not underwritten, was considerably over-subscribed. These were by no means favourable times for floating an issue, and it afforded great satisfaction to the directors to know that the undertaking was held in such high esteem by the shareholders. The loan account of £45,000 was as against £41,000 last year. The total capital expenditure amounted to £487,949, and of ever, a source of keen satisfaction that they were able to sub-The total capital expenditure amounted to £487,949, and of this the net sum of £14,552 had been expended in the past year. The gross expenditure was £28,773, the difference being year. The gross expenditure was £28,773, the difference being accounted for by machinery written off during the year. By far the larger portion of that expenditure was represented by additions to machinery and plant at their Bourne Valley station, viz., £16,189. The main extensions were £8,285. They had an extensive and excellent area of supply and one that was developing daily in all directions. They had advanced a further £2,250 to the Richmond Co. on loan and taken up 2,570 ordinary shares of £1 in the Dorset Electric Supply Co. Ltd. In the revenue account the results were quite satisfactory. There was an increase of £3,839 in receipts for the sale of current and meter rentals, and of £281 in the interest and dividends, mainly due to the increased return from the com-pany's holding in the Richmond Co. A decrease of £126 was shown in the profits of their trading account which, to some extent, was explained by the fact that a larger sum had been charged for standing charges, etc. This department, however, was most useful in developing the company's business, and they did not desire to cut prices or compete rigorously with local engineers and contractors. The only item he would refer to on the debit side of the revenue account was that for even and other fuel, which had increased by 6759. coal and other fuel, which had increased by £758. They had sold 242,504 more units, or nearly 7 per cent. increase, and in common with other companies who were large users of coal common with other companies who were large users of coal they had suffered from the rise of price since the beginning of the war. They had had difficulty in maintaining their usual large stock, but so far had succeeded in doing so; but as the result of these difficulties they were paying on the average 8s. per ton more for coal. They had written off £7,000 for depreciation, as against £6,000 in the previous year. To summarise the results, an increase of £3,602 was shown in gross revenue; the total sum written off out of revenue in respect of reserve was £739 up for the year, being £40,039 against £38,284 brought into the account; the dividend of 7 per cent. Was the same as last year: the carry forward was per cent. was the same as last year; the carry forward was increased by £1,684, which was equal to a further 1 per cent. on the ordinary share capital; the applications for a supply of on the ordinary share capital; the applications for a supply of current received during the year amounted to the equivalent of 874 kw., as compared with 504 kw. for 1913; and the units sold were 3,910,511 against 3,668,007 for 1913. With regard to the Richmond Co., they held shares and debentures and loans representing an investment of £122,750. They were greatly indebted to their Managing Director, Mr. Renwick, for the skilful manner in which he had carried through most difficult negotiations with the Richmond Corporation whereby the company had secured an extension of the period of purchase for a further 30 years, which made the unexpired term 36 years. This was a most remarkable achievement when they realised that the terms were regarded as most advantageous realised that the terms were regarded as most advantageous to the Corporation, whilst, so far as the company was concerned, their investment was immensely strengthened. The cerned, their investment was immensely strengthened. The concession was secured without any cash payment. The company was now taking a bulk supply from an outside source, the economy of which had already resulted in a small increased profit, and would result in bigger dividends at no distant date. Returning to the Bournemouth and Poole Co., last year he told them the Board had decided on the policy of installing new plant at the Board had decided on secretary station. installing new plant at the Bourne Valley generating station, installing new plant at the Bourne Valley generating station, from which vast economy in running might be secured. A turbo-alternator of 1,000 kw. capacity was installed and brought into use at the end of September, whilst a second unit of the same size was brought into use at the end of October. This plant had been in use a sufficient time for the board to satisfy themselves that the large outlay of £16,000 would effect economies quite equal to their anticipations. Comparing January and February of 1915 with the corresponding months of 1914, whilst a considerably greater output had been obtained the consumption of coal was 800 tone less had been obtained the consumption of coal was 800 tons less. The saving thus effected meant a saving of 44 per cent. of the quantity of coal previously used, and there were other

Digitized by Google

economies in lubricants, etc. Doubtless they could secure further economies and better distribution of their electric current if additional new plant was installed, and he felt confident it would be found desirable and financially sound to extend their up-to-date plant to deal with Christchurch at no distant date. The Chairman proceeded to refer to the board's indebtedness to Mr. Sparks (the consulting engineer), Mr. E. L. Ingram (the engineer), and Mr. W. D. Brightman (the secretary). With regard to the prospect for the current year, they had no reason to be downhearted, for the business was maintaining satisfactory processes. Sixty-two pays conwas maintaining satisfactory progress. Sixty-two new consumers had been connected since January 1st with a demand of 46 kw. for lighting and 98 kw. for power and heating, and the weekly estimated consumption during the present year showed a satisfactory increase over the previous year. They had now 7,616 consumers connected. Seventy-six of their staff had been called up or enlisted, and the board were making adequate provision for their dependents, which would cost stan had been caned up or emisted, and the board were making adequate provision for their dependents, which would cost them £600 a year.

Mr. F. W. REYNOLDS seconded the motion and it was agreed

to without discussion.

#### Listowel (Co. Kerry) Electric Lighting Co., Ltd.

The second annual meeting was held recently. Mr. J. Macauley, who presided, said that the year had been most satisfactory. The gross profits amounted to £2%. Although they were in a position to pay 7½ per cent. on the capital, the directors considered that at present it was not advisable to do so, and they proposed that £150 should be set aside for depreciation reserve, and that a dividend of 7 per cent. be declared, carrying forward the balance. The number of consumers had increased from 175 to 197, but there was a falling off in receipts from individual consumers, due to greater economy in lighting. They had secured a very large portion of the private lighting of the town, and they were considering how to still further extend the business. The contract for pumping water to the reservoir for the town supply had been how to still further extend the business. The contract for pumping water to the reservoir for the town supply had been laid down to deal with it. It had now been working about seven months and had given satisfaction. They had shown a considerably increased output of current at a reduced cost per unit. The average price obtained for current was considerably lower than that for the previous twelve months. Both the cost of generating the current and the price charged compared favourably with other towns in the South of Ireland. He believed that Listowel was the only town in Munster of its own size where current was available at 5d, per unit. Owing to the heavy demand they were installing additional reserve plant. reserve plant.

#### British Westinghouse Electric and Manufacturing Co., Ltd.

The directors report that, notwithstanding abnormal conditions arising out of the state of war, the accounts for 1914 show a continued improvement. The net profit amounts to £151,627, plus £6,494 brought forward, making £158,121. This is to be appropriated as follows:—To general reserve £50,000, to patents, goodwill, etc., amount written off, £25,000, dividend on preference shares at the rate of 7½ per cent. £75,000, to be carried forward £8,121. The net profit is considerably in excess of that in 1913, when it amounted to £106,494. Substantial sums have again been charged against revenue for the maintenance of the works and plant, and in addition £50,846 has been applied to depreciation. Since the end of the year under review the company has acquired from the American Westinghouse companies their interests in the French, and through it the Italian, Westinghouse companies. The board believe that this extension of the company's business will be profitable.

The profit and loss account shows that the gross profit for the The profit and loss account shows that the gross profit for the year, including estimated profit accrued to date on completed work on contracts, interest received, transfer fees, etc., after providing for expenses of management, directors' fees, bad and doubtful debts, maintenance of buildings, machinery, etc., and all other working charges, was £267,819. This has been dealt with as follows:—To interest on 6 per cent, prior lien debentures to 31st December, 1914, £12,870; to prior lien debenture redemption account, £7,130; to interest on 4 per cent, mortgage debenture stock, £49,654; to expenses on surplus land and buildings, £2,822; to depreciation written off works, machinery, plant, etc., £43,716; to balance, being net profit for year, £151,627.

### British Aluminium Co., Ltd.

THE trading profit for 1914, together with interest and divi-The trading profit for 1914, together with interest and dividends on investments and deposits, and the revenue derived from Kinlochleven and Fovers Estates, and transfer fees, was £272,256, plus £16,690 brought forward. Provision for income tax, legal expenses, bad and doubtful debts, depreciation of investments and furniture, and proportion of profits payable to directors, absorbs £24,966, prior lien debenture service fund £48,000, debenture stock service fund £43,224, reserve for

depreciation £50,000, carried to reserve account £50,000, leaving £72,756. The dividend at 6 per cent. per annum on the preference shares requires £17,974, and the directors recommend a dividend of 5 per cent. per annum, less tax, on the ordinary shares, payable 1st April, 1915, requiring £30,031, leaving to be carried forward £24,751. The reserve account, including £50,000 added out of profits for the year, amounts to £180,000. Owing to the necessity of making provision for capital expenditure, the allocations to this account for the last two years have not been invested outside of the company's business. The depreciation reserve account, including £50,000 set aside out of the year's profits, now stands at £200,000. The various works of the company have been operated satisfactorily during the year. The power plant for the rolling mills at Warrington has been completed, and the preliminary work for the erection of the new Alumina. Works at Burntisland is in progress, and contracts have been placed depreciation £50,000, carried to reserve account £50,000, leavat Burntisland is in progress, and contracts have been placed for a large part of the buildings and plant required. The erection of further plant for the extension of the manufacture of purpose about soles at Vislands large in proceedings and will for a large part of the buildings and plant required. The erection of further plant for the extension of the manufacture of carbon-electrodes at Kinlochleven is proceeding, and will be completed in the course of the year. The output and sales show an increase over the previous year. Prices are approximately on the same level as last year, but the cost of production has been affected towards the end of the year by the increased prices of certain materials, freight, and insurance. The war has necessitated the cancellation of considerable orders and contracts on the company's books with certain Continental users, but this has been off-set by the increased demand of the British Government and its Allies, and contractors working for them. The demand for the metal continues to increase, but, owing to the abnormal situation created by the war, difficulties are now being experienced in connection with supplies of raw material and coal required by the various works, and the costs of production are being adversely affected by the increase in labour charges, coal prices, freights, insurances and other expenses. In view of the difficulties above mentioned, the board feel that, notwithstanding the improvement in profits for the year, it is prudent that the dividend on the ordinary shares of the company should not be increased.

Annual meeting: March 26th.

## STOCKS AND SHARES.

TUESDAY EVENING.

The present situation at the front and in the Dardanelles contains nothing of what might be called sensational interest, sufficient to quicken Stock Exchange markets. Even in these days, when there is no speculation and business is confined to the humdrum lines of investment, the character of the news from the front does make a considerable difference. Lord Kitchener's grave warning on the necessity for workinen at home to back up in the shops the efforts of their comrades in the Sarvices added to the agricus museum giralleting in the home to back up in the shops the efforts of their comrades in the Services, added to the serious rumours circulating in the City this week, have provided food for reflection to those who gaily declared that the war was going quite all right and that its conduct could be left to those already engaged in it. Armament shares have given way in consequence of the growing impression that the Government will take over the companies, pay shareholders a fixed rate of dividend, and run the concerns in the same way as they are doing the railways

companies, pay shareholders a fixed rate of dividend, and run the concerns in the same way as they are doing the railways and the wireless systems. The report of the British Westinghouse Co. shows fine progress, and that issued by the Brush Electrical is fairly satisfactory.

Electricity supply shares have shown a drooping disposition, notwithstanding the expansion in the matter of public interest. St. James' fell abruptly to 81, and London Electric preference at 4 15/16 are 1/16 down. County preference came in for fresh attention, by reason of the good yield still obtainable on the shares at the present price of 111. There are buyers about for South London and for South Metropolitan ordinary—the latter in the neighbourhood of 10s., while for the former would-be purchasers at 2 15/16 ex-dividend have the former would-be purchasers at 2 15/16 ex-dividend have found they could not be supplied.

Rumour toys with the idea that there may be something

brewing in the shape of amalgamation or working agreement between certain of the London companies. The South London and the South Metropolitan are already mentioned in connection with this, and their names are linked with that of one of their bigger brethren, though the gossip is still too nebulous for it to be referred to in a way other than this years fashion.

of their bigger brethren, though the gossip is still too nebulous for it to be referred to in a way other than this vague fashion.

The Stock Exchange, by the way, was a little alarmed a week or two ago, because its supply of coal seemed to be threatened by the all-round scarcity. The House makes its own electricity, and its fuel consumption is something like twenty tons a week in the winter months. Its bunkers contain reserves of about a month's supply, which have not yet been touched, although the managers contemplated the possibility of having to raid their eighty tons while the acute scarcity of coal prevailed. scarcity of coal prevailed.

With the gas companies raising the price of their commodity, it would be at least comprehensible if the electric undertakers had to follow suit, so that the reports as to the possibility of this taking place might have something more in them than mere intelligent anticipation.

Digitized by Google

Metropolitan Consolidated stock has gone back to 291, and Districts to 17, but Underground Electric incomes keep hard about 31. The tendency of the railway market as a whole underwent a change for the better a few days ago, but since then, prices relapsed into dullness again on the cessation of the few buying orders which imparted temporary strength to the market.

The Treasury have consented to a lowering of the minimum prices fixed by the Stock Exchange Committee, and below which brokers were not allowed to sell stock. The following are the principal changes affecting electrical issues:—

Railway Stock,	М	inimu	m.	Reduction.	
	Previous.		Present		
Central London 4 p.c. debenture .	95		93		2
London Electric debenture					
Metropolitan 31 p.c. debenture	85		831		17
Met. District 4 p.c. P.L. debentur	e 94		92		2
Metropolitan 31 p.c. preference	<b>7</b> 9		771		12
Metropolitan "A" preference	76		741		13
Metropolitan Conv. preference	76		741		12

The reduction in the minima, which was preceded by such heated controversy from those who favoured it and those who did not, has had some little effect in improving business. At did not, has had some little effect in improving business. At first, the result was directly opposite from this; but as the markets concerned have become accustomed to the new prices, so orders have increased. It is, of course, only in the gilt-edged markets that this system has been applied. Consols, for instance, were lowered from 68½ to 66½; and many trustee stocks came down from two to four points. The Treasury have intimated that they will not permit any further variations to be made during a period of at least three months.

The following is our list of representative stocks and shares:

In the Telegraph market, activity centres for the moment principally in Anglo-American Telegraph deferred stock, which has rise to 21½ on a fair amount of investment buying. The Eastern group is tolerably steady, but Westerns lost their 5s. rise of last week. Globe preference continue to harden, and are now up to 12. Marconis eased off 1/16, which took the price back to 35s., while the subsidiaries are practically unchanged. The company's preference shares keep about a florin a share below that for the ordinary.

Brazil Tractions show a dullish disposition, which possibly may be connected with the approach of the time when the next dividend declaration is due. The market is becoming calloused to these quarterly apprehensions; and if the directors should happen to decide to cut the dividend, advance familiarity with such an idea may have the effect of preventing any particular fall occurring as a result. Mexico Trans 5 per cent. bonds receded another 5 points to 45, so that the price is almost exactly half what it was when war broke out. Affairs in Mexico are no better, though a gleam of satisfaction may be felt by holders of Mexican securities that New York should be buying shares in certain of the Mexican railway concerns controlled from the United States.

British Westinghouse preference rose to 40s., and there has been a good deal of business at prices from 6d. to Is. above that level, owing to the excellent report just issued by the company. It was expected that the British Westinghouse would be seen to have done well, but the actual figures exceeded anticipation; and a good deal of fresh support has come into the market. Brush issues are not much affected by the company's shares remain steady at 14s. 6d. The rubber market exhibits quiet strength. Those who try to buy good-class shares find it extremely difficult to do so; and with two or three companies publishing reports this week in which they show that their costs are reduced to 9d. or 10d. per lb., it is not surprising that there should be enquiry for

#### MARKET QUOTATIONS.

In last week's issue, through a figure failing to print up, the price of aluminium sheet in ton lots appears as £20 per ton. It should, of course, have read £120.

Folkestone Electricity Supply Co., Ltd.—At the annual meeting held on March 19th, the Chairman (Ald. Spurgeon, J.P.) congratulated the shareholders on the very successful year's business. £11,696 had been spent during the year, principally upon a new 500-kw. Parsons exhaust turbine, condensers, and pipework. The revenue for the year showed an increase of £1,212; the working expenses were reduced by £322, and the gross profits were £1,534 in excess of 1918. They had used less coal in the year by 806 tons (resulting in the saving of £813) although there had been an increase of 88,000 units. This saving he attributed to the advent of Kent coal and increased efficiency of plant. The future coal supply was not entirely satisfactory, although the conto the advent of Kant coal and increased efficiency of plant. The future coal supply was not entirely satisfactory, although the contracts for the present year were favourable. The amount available for dividend was £13,099, as compared with £11,348 in 1913—an increase of £1,750. Only on one occasion in 1912-13 has this increase been exceeded, and then it was £1,921. During the year 233 additional consumers were added, being equivalent to 6,843, 8-C.P. lamps, the total being 145,943 lamps; 2,333,415 units were generated, and 1,753,330 sold. The chairman added that the directors were continuing the system of bonuses which had been in force for two years, and they also were naving those symplops. in force for two years and they also were paying those employés who had joined the Colours the difference between the pay they received and their earnings at the works. The company had arranged to supply the adjoining town of Cheriton with electric light.

#### EXPORTS AND IMPORTS OF ELECTRICAL GOODS DURING FEBRUARY, 1915.

THE February returns of electrical export and import business make a poor showing beside those of the previous month, which even the shortage of days will scarcely account for.

The electrical exports for the month reached a total value of £256,519 as compared with £364,562 in January, which, however, was a good month under the circumstances. The imports of electrical materials were valued at £217,500 as against £239,127 in the previous month, while the re-exports had a total value of £22,216, showing an improvement over the January total of £12,455.

Practically every section of our electrical export hashes.

Practically every section of our electrical export business fell

off in value, the only exception being glow lamp exports, which were £2,000 to the good. Of our various customers, India was the most prominent, while France probably owing to prevailing onditions occupied second place; Australian business also restricted. good proportions.

The only sections of the imports showing any increase over the January figures were goods, batteries, and particularly glow lamps, due to the inclusion of nearly £15,000 worth from Holland.

The United States was the principal contributor to the imports total, and business in that direction decreased from £198,596 in January to £171,696 in the month under review.

Note.—The amounts appearing under the several headings are classified according to the Customs returns. The first and third column contains many amounts relating to "goods" otherwise unclassified, the latter, doubtless, consisting of similar materials to those appearing in adjacent columns. Imports are credited to the country whence consigned, which is not necessarily the country of origin.

# RUSSIAN TRADE AND ELECTRICAL PROSPECTS.

(COMMUNICATED.)

(Concluded from page 416.)

In the matter of credits, German firms have ever been most obliging, backed as they have been by their banks. In Russia, as an agricultural country wherein money flows chiefly in the seasons of sowing and harvest, six months credit is usual and twelve months often demanded. The numerous cooperative societies (mentioned again later) are doing a good deal to provide agriculturists with ready money at other seasons, but the broad fact remains that any firms exporting to Russia must be content to wait six months or so for payment; there is rarely any objection raised to reasonable payment for this accommodation. For a good many years to come, Germany will not be able to give such preposterously long credit as she has often employed in the past to win business in undeveloped countries.

Russian import duties are framed on a weight basis*, and, whereas many British manufacturers send in heavy machinery complete and therefore subject to heavy tax, German firms have evolved special types for export, and have arranged to make and fit heavy castings, etc., within the Russian frontier. Ironically enough many of the "factories" built by Germans to comply with the letter of Russian law, are simply private foundries and assembly shops serving to evade by one means or another a considerable portion of the customs dues paid by less astute or less efficiently organised undertakings. Under the existing tariff it is obviously foolish to pay freight and customs charges on heavy frame castings, etc., which can be as well made in a branch factory on the spot. The establishment of such a factory gives prestige and affords a good centre for a local representative or a more ambitious staff of travellers.

It is practically certain that there will be substantial mutual tariff concessions between the Allies after the war, and our gain in this respect would obviously be greater if we had a tariff of our own on which to offer concessions. Apart from this consideration, anyone who has made more than the most casual study of measures taken since last autumn to "capture German trade" must realise of what immense assistance would be a protective tariff to our newly-founded industries. Without it, some industries cannot possibly compete with established and protected German trade.

We shall not secure the Russian electrical or any other market unopposed. During the war we have a temporary respite from German commercial activity abroad, and now is undoubtedly the time to prepare a commercial campaign in Russia. Almost every firm here is choked with war orders. Necessary and urgent as these are, they represent national expenditure and not national production, and while we are engaged upon them we must see that the rivers of our peaceful commerce become neither silted nor diverted. America realises the importance of the Russian market, and an American firm with a factory in Russia has a good share of the electrical business in the Baku oil fields.

Just at present we have easier access to Russia than most neutrals, but even so it is not wise to start circularising Russia at the moment, for postal delays are considerable (a registered letter dispatched from Petrograd early in February taking nearly a month to reach England). With the opening of the Dardanelles a revival in Russian trade will occur, and as there is already a great shortage of electrical material in Russia, it is not a moment

too early to plan the measures which are to be taken directly an easy trade route is opened. There has been much talk of a new Scandinavian trade route to Russia to replace permanently the old Berlin route. Whether the suggestion will mature is open to doubt, but it has at any rate caused considerable annoyance in Berlin!

The Scandinavian route leads to an important industrial area, but is long and without particular merit. Given neutralisation of the Kiel Canal and some more Baltic seaboard for Russia—both quite probable contingencies—the all-sea route would seem well worth while for all but the lightest traffic, and would not be so much longer than that for the Scandinavian route, while avoiding the long rail journey and a large fraction of transhipment costs.

It is difficult to foresee precisely what will be the labour position in Germany after the war, but no doubt it will be characterised by long hours and low wages, and no doubt it will constitute a serious factor in the competition we shall have to meet. However, there is no cause for despondency—only need for improved organisation in manufacture and selling to set the balance right. America competes effectively in every market despite her very dear labour. It is surely time, however, that the British working man saw clearly that strikes are literally "bad business." The heavy union levy is dissipated in a few weeks of strike pay, trade is disorganised, and national production is inevitably given an irrevocable set-back. Usually some advance in wages is obtained, but the strike is not a success for the resulting increase in market price reacts sooner or later to the disadvantage of workers, and better organisation and better machinery are introduced to decrease the wages cost for given production despite the higher wage rate. The final upshot is that the net profit to the striker is very small but he has to work under strenuous conditions. The fact is that capital will have a certain minimum return or it will go elsewhere. Compulsory arbitration in labour disputes is long overdue, would only be in conformity with ordinary civil law, and would greatly strengthen our position in the years of keen competition that are to come.

In turning from consideration of the general electrical trade field in Russia, and the means whereby it is to be secured, to a specific review of the exact nature and extent of Russian electrical developments and demands, we are faced by the difficulties that imperfect statistics are available; that during the last year or two innumerable fresh schemes have been mooted, some abandoned, and some far developed (mostly under the cloak of German organisation); and that the past development will be as nothing compared with that yet to come. So far the Russian electrical industry has centred round Riga, Petrograd and Moscow, but recently there have been very extensive developments, actual and mooted, in the Baku district, in the Urals, and in Siberia, so that with rapid improvements in ways and means of communications electrical development will proceed rapidly all over the Empire.

Some 60 per cent. of the 150 most important central stations are managed municipally; the remainder are operated by concessionaires, chiefly in industrial districts, and supply about 10 million population (twice that served by the municipal concerns). There is, however, an enormous field for municipal enterprise in water and electricity works and tramways, and for State enterprise in electric railways and hydro-electric schemes. Municipalities and State departments seem thoroughly alive to these possibilities and display preference for electrical operation wherever practicable. By its agricultural and mineral wealth the country is able to afford large public undertakings which will have as their first effect rapid industrial development.

The present unsatisfactory position under electrical companies in Petrograd will be much improved

^{• £2 15}s 10d, per cwt. on dynamos, motors and transformers; £3 18s, 10d, per cwt. on measuring instruments: £9 17s, 0d, per cwt. on incandescent lamps mounted, and £19 14s, 0d, per cwt. unmounted.

by municipal purchase, schemes for which are already far advanced, though, due to the war, they will probably be suspended till the right of purchase falls due in 1917. The central station in Moscow, controlling the great Bogorod industrial district, has been repeatedly extended since its inauguration nearly thirty years ago. The maximum load has roughly doubled in every five years' period since 1901, and now exceeds 30,000 kw. The present station is a two-story building with efficient equipment, totalling 55,000 kw. capacity and supplying two thirds of its output to feetones and workshops two-thirds of its output to factories and workshops. The usual supply system in Russia is generation and main distribution at 2,000—2,200 volts, 3-phase, with 100-220 v. transformers supplying groups of con-No better system could be employed under sumers. the conditions to be met, indeed, the relatively low lighting pressure would be very acceptable in this country since the introduction of metal and half-watt lamps. Seven years ago the generating and main feeder pressure in Moscow was raised from 2,100 to 6,500 v. to suit extended and increased supply, and it is an advantage of A.C. distribution that by adding fresh main feeders and transformers such increases in primary pressure can be continued indefinitely.

Plenty of water power is available on the Urals for hydro-electric development; conditions will permit economical and strictly utilitarian construction, and a base load is already to hand in the mining districts. Concessions have been granted for the supply of traction, lighting and power to the whole Petrograd and Viborg district from the Imatra-Raisala falls, one of the largest undeveloped waterfalls in Europe, capable of yielding somewhere about 500,000 horse-power. The £125,000 loan sanctioned for a lighting and power station in Nijni-Novgorod is another little matter deserving the attention of

British firms.

The municipality of Kieff (where there is already a 12,000 kw. plant on the usual Russian system, supplying 10,000 consumers) has in hand a loan of £2,500,000 to purchase and extend tramways, and a half-million loan is approved from tramways in Vilna. The Vladivostok tramways, at present working successfully despite the limited facilities which they provide at exorbitant fares (4d. to 5d. a mile), are to be extended and reorganised, and a large number of traction schemes are more or less advanced in Siberian towns. Belgian enterprise has been very active in Russian tramways (especially in Siberia and Central Asia) but no one would begrudge our Allies their share in this business, there is room for all—except Germany. The State Commission for New Railways is an active body, and has a number of important schemes in hand for electric railways radiating from Warsaw, as well as an electric railway from Vladikaykaz to Tiflis, and a 1,200-mile line from Irkutsk to Bodaibo. Electric power is much used in the State railway shops and electricity is to be used for lighting on the railways.

Very extensive telephone and telegraph additions are required. This business has been mostly shared by Swedish and German firms, and there is no reason why British firms should not compete very effectively in future.

RUSSIAN ELECTROLYTIC MANUFACTURES, 1913.

•	90,050	£3,169,000	

Electrochemical and metallurgical manufacturers in Russia represent a very extensive and remunera-

tive industry, 100 per cent. net profit being realised on much of the capital invested. Unfortunately, much of that capital has been German in the past. Russian electrolytic manufactures in 1913 are reported in the table given in the previous column.

The steadily increasing demand for electrolytic copper for railways and electrical undertakings is met by Mm. Rosenkranz, of Petrograd, and the Kyshtim Corporation, new plant recently installed by the latter bringing their total capacity up to

8,000-9,000 tons per annum.

Among the most promising electrical fields in Russia are those of electricity in agriculture and power supply to peasant industries. The very active spirit of co-operation in Russian farming and dairy districts should do as much to help the extended use of electric motors in agriculture as co-operation has already done in Canada and the States. are more than 30,000 co-operative combinations of Russian farmers already in operation, apart from important State co-operative schemes. A co-operative society can afford equipment beyond the reach of individual farmers, and can secure commensurate advantages to the whole community and equal benefit to electrical manufacturers and supply stations. Already these societies have done much in the way of purchasing tractor ploughs and thrashers, and the impending inauguration of new power transmission schemes, and extension of existing central stations, will produce opportunities which should not be neglected for the use of electricity in agriculture. British manufacturers could very profitably lay themselves out to exploit at the same time the use cf electric power and lighting in our own and in Russian farming districts. Large numbers of oil engines are used and will be used in Russia, and since British agricultural machinery and oil engines are already well known in Russia. and since electrical equipment would be required to work with one or both of these (according as power was taken from central or independent supply), there would seem to be room for very effective combination between British manufacturers of agricultural machinery, electrical equipment and oil engines. Without such cooperation there must be much unnecessary competition and all-round inefficiency. For a time, the chief demand is likely to be for medium high tension (2,000-3,000 v.) equipment and low tension (120-240 v.) transformers and lighting and power apparatus. The more special field for E.H.T. equipment will be extensive but not of immediate interest to the general manufacturer.

With a view to enabling peasant industries to continue their independent existence, State and municipal departments are taking considerable interest in rural distribution schemes for electric power, and there is reasonably to be expected a deal of business in this direction.

The past dominance of German capital and influence, and the drastic measures adopted to thwart attempts to establish independent electrical concerns in Russia, have been felt very keenly in influential quarters, and there is a movement on foot (which might advantageously be copied in this country) to execute all public electric requirements in Russia by Russian material and labour where possible, and in any case free from German profit and control. The establishment of independent Russian concerns and the granting of industrial credit by the Russian Imperial Bank will be very effective in promoting free international trading and rapid industrial development in that country. Electrical development will be among the most important branches of this general industrial advance, and there is not the least doubt that Russian firms and authorities are very wishful to trade more extensively with British manufacturers. Such a ready-made market as never before existed lies open to us, but the special advantages we enjoy can only persist unaided for the immediate future, and the time for action is now.

#### ELECTRICITY APPLIED TO MINING.

#### BY C. P. SPARKS, M.I.E.E.

(Abstract of paper read before the Institution of Electbical Engineers, February 25th, 1915.)

#### (Concluded from page 422.)

Distribution Underground.—In contrast with some other countries the working conditions in the British coal fields require all conductors to be insulated, and in order to prevent damage due to movement in the workings all conductors are usually suspended by leather thongs. To ensure continuity of supply for important pumping plant duplicate double-wire-armoured cables are used, either placed on opposite sides of the shaft or preferably run in separate shafts so as to prevent the supply being interrupted by mechanical injury.

Earthing Connections.—Whilst recognising the difficulty of specifying how an efficient earth connection should be made, the author is in agreement that the main "earth" must be placed at the surface of a colliery owing to the difficulty of constructing and maintaining efficient earth-plates underground. The usual power-station practice should be followed Distribution Underground .- In contrast with some other

constructing and maintaining efficient earth-plates underground. The usual power-station practice should be followed in which several earth connections are made by a copper ringmain connected to steam condensers, circulating-water pipes, feed pipes, and other metal-work in direct connection with earth, or, in cases where it is not possible to make such an earth connection, the contact area of each coke bed should be materially greater than that specified in the General Regulations issued under the Coal Mines Act, 1911, the coke bed being carried down not less than 8 feet below ground-level. From tests on main station "earths" constructed on the lines indicated, the measured resistance to earth with alternating current at 50 periods varies in representative cases from 0.01 to 0.03 ohm.

indicated, the measured resistance to earth with alternating current at 50 periods varies in representative cases from 0.01 to 0.03 ohm.

Tests made on earth-plates constructed on the lines recommended by the General Regulations under favourable conditions as to moisture, vary from 1.8 to 2.2 ohms. If the conditions are not favourable a much higher resistance to earth will be found, as the resistance to earth is directly affected by the amount of moisture, unless precautions are taken to supply earth-plates with moisture and periodically to impregnate the surrounding strata with salt. Tests show that this treatment is effective in lowering the resistance of poor earth connections.

Tests have been made on groups of earth-plates in different localities, constructed on the lines recommended by the General Regulations. The tests show that the size of the metal earth-plate is comparatively unimportant compared with the area of the coke bed. With a plate of 8 sq. ft. area surrounded by 12 inches of coke, the surface contact of the coke with the surrounding strata is about 40 sq. ft. which results in the resistance between the earth-plate and the outer surface of coke being approximately 0.5 per cent. of the total resistance to earth, with the coke bed surrounded by clav.

The tests show the desirability of burying the earth-plates at considerable depth so as to avoid too great a potential gradient on the surface.

Tests show that if a main "earth," consisting of two earth-plates constructed under favourable conditions on the lines

gradient on the surface.

Tests show that if a main "earth," consisting of two earth-plates constructed under favourable conditions on the lines recommended by the General Regulations issued under the Coal Mines Act. 1911, had been called upon to carry a current of 500 amperes for a short period, such as that necessary for a circuit-breaker to operate, the potential at the earth-plate would have been not less than 500 volts above earth. Any such pressure on the earth-plates, although of momentary duration, is dangerous, as it would result in the cable sheathings and any metal connected to the main "earth" being raised to a dangerous pressure. It is therefore essential that a different type of main "earth" should be used from that recommended by the Regulations, or else that the number of earth-plates be increased.

recommended by the Regulations, or else that the number of earth-plates be increased.

Earthing of Sustem.—Safety has been much increased by the Regulations issued in 1913, which provided that all conductors where pressure exceeds low pressure (250 volts) must be protected by a metallic covering electrically continuous and efficiently earthed; but the author suggests that when the Regulations are next under revision Regulation (124) should be amended so as to make it compulsory to earth the neutral point of all polyphase systems. The main advantage of working with one point definitely earthed is the impossibility of continuing working with a definite fault on the system.

Suitchacar.—At Middle Duffryn power station the switchgear, which is erected in a separate building, is operated electrically by remote control from a 110-volt battery. The bushars are arranged as a ring, which can be split by two 2,000-ammere oil-break motor-operated switches. For repairs, each

anthere oil-break motor-operated switches. For repairs, each half of the busbar ring can be subdivided by unbolting links. The generators are protected by balanced protective transformers, connected between the neutral and each phase, and by time-limit, overload and reverse-current devices. The feeders are protected on the Merz-Price system and by time-

limit overload apparatus.

The switchgear at Penallta station is mechanically operated by levers, the switchgear being in the basement (see fig. 10). The generators are protected by time-limit, overload and reverse-current relays, the feeders by time-limit overload, and the overhead transmission lines and transformers by time-

limit overload and the Merz-Price system.

At Britannia Colliery the switchgear is erected in an annex and the winder house, the switches being mechanically operated and the control pillars being on the floor-level. The busbars are arranged as a ring, which can be separated into two halves by 400-ampere oil switches, each section of the ring being again divisible for repairs by unbolting links. When the ring busbar is divided, each section of the bar has direct connection with the Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle and Parelle tion with the Penallta and Bargoed stations, and a supply can be given from either section of the busbars to one main winder and to the 10,000/3,000-volt transformers which supply the remainder of the colliery plant. The 3,000-volt busbars are remainder of the colliery plant. The 3,000-volt busbars are treated in a similar manner.

At Bargoed the busbars are in duplicate, the generators and

feeders being connected to either of the busbars through inter-locked isolating switches. The protective arrangements are as

follows:

Generators.—Time-limit overload and reverse-current relays. Feeders.—Time-limit overload and Merz-Price protective

system.

The pressure is controlled at the power station by Tirrill regulators. This has resulted in an improved power factor on very fluctuating loads. Having regard to the variation of 25 per cent. in load in either valley in a few seconds, it was found difficult to maintain a satisfactory pressure until the plant at the various power houses was controlled by these regulators. regulators.

The power factor varies between the following limits:—

Aberdare Valley ... Rhymney Valley ... ... 0.7 to 0.85 ... 0.7 to 0.8 ...

The generators are constructed so as to give their full output with a power factor of 0.75. Owing to the moderate distance of transmission there has been no difficulty in maintaining the normal pressure at the individual collieries, but in order to deal with further extensions some of the larger motors

will probably be fitted with power-factor correctors.

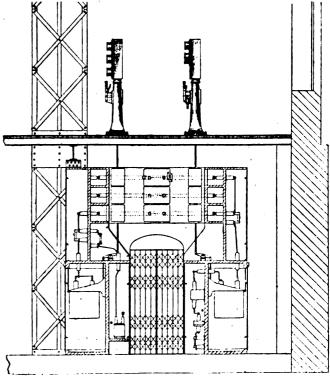

FIG. 10.-10,000-VOLT SWITCHGEAR, PENALLTA AND BRITANNIA COLLIEBIES.

Motors.-Originally all motors were controlled by screened motors.—Originally all motors were controlled by screenes panels, the high-pressure parts being protected by earthed metal screens, interlocked with the isolating switches. This type of switchgear is now displaced by pillars of rigid metal containing the isolating switch, oil switch, overload relays, eries transformers, and ammeter, the isolating switch being interlocked with the cover which gives access to the switch-

All motors are controlled by overload relays actuating the oil switches. This gives definite protection and enables the supply to be renewed with a minimum of interruption; it also avoids the risk of fuses of the enclosed type being replaced with unprotected metal.

Lighting.—Underground this is confined to the immediate pit bottoms, and the haulage and pump rooms. The standard pressure is 110 volts, carbon-filament lamps being used.

The conductors are single rubber-insulated cables in stout, screwed, metal conduits, and are controlled by switches and fuses in cast-iron watertight boxes, all lamps being enclosed in patentight fittings. in watertight fittings.

The Powell Duffryn Co, have now between seven and eight

thousand miners' electric lamps in use, or about two-thirds of

These lamps weigh about 51 lb. each, compared with 31 lb. for the standard oil safety lamp, and they are welcomed by the miners, who prefer the additional illumination in spite of the additional weight.

The lamp batteries are charged in groups of 40 for lead and 26 for alkaline batteries by 116-volt continuous-current motor-generators, each charging stand having an ammeter and a variable resistance for adjusting the current.

At the larger collieries charging boards capable of holding 1,000 batteries are used, the lamps being stored in a standard rock in the larger core, then charged.

rack in the lamp room when charged. In the first instance the lead batteries were charged in seven hours; this is now extended to twelve hours. During charge the lead batteries are inspected to see that they are gassing, and on the completion of the charge the pressure of each is tested by a postuble voluntary. During charge

and on the completion of the charge the pressure of each is tested by a portable voltmeter.

With normal charging, the lamp will burn 12 to 14 hours. The candle-power is between 1 and 14, depending upon the condition of the battery and of the type of bulb; whereas the ordinary oil safety lamp gives 0.5 to 0.6 candle-power.

The energy required for charging is of minor importance, and the cost of attendance for charging and cleaning the electric lamps is comparable with the cost of the daily attention

ric lamps is comparable with the cost of the daily attention necessary in the case of ordinary oil lamps. The important part of the cost is the maintenance of the battery and the lamp bulbs. In the case of the lead battery, the cost of lamp renewals equals the cost of battery maintenance.

Two types of battery are used. With the original lead type the positive plates leated about nive mention registers.

Two types of battery are used. With the original lead type the positive plates lasted about nine months; new positive plates were then inserted to run a further nine months, before the negative plates required renewal. Improved positive plates are now on trial, and it is hoped that they will last eighteen months. The main-point necessary for success with the lead type of battery is the non-spilling of acid. Cleanliness is

everything.

The alkaline type of battery is now under trial. these are twice as expensive as the lead type, their life is very much longer. Sufficient time has not yet clapsed to allow the life to be definitely determined, but the makers give

it as 15 years.

When it is possible to use lamps of the half-watt type, the useful field for miners' lamps will be much extended, as the batteries will then have to be charged only half as often as at present, with consequent decreased wear and tear, or, alternatively, increased light will be obtainable without adding to the weight.

In addition to the miners' lamp a second type is being tried or officials and hauliers. In this case the battery is strapped for officials and hauliers. to the man's back and the lamp is fixed in his cap so as to

leave both hands free.

In all positions where there is danger of gas the present type of electric lamps have to be supplemented by oil safety lamps, so that there may be a clear indication of danger.

Electric Signalling.—The increasing size of colliery undertakings and the use of haulages renders electric-bell signalling important. This system has been in use for about 25 years, and while its reliability in signalling over comparatively long distances has led to a decrease in the number of accidents its

and while its reliability in signalling over comparatively long distances has led to a decrease in the number of accidents, its safety has been questioned during the last two years.

Following an explosion of fire damp in the South Wales district in 1912, a notice was issued by the Home Office stating that "The explosion was proved beyond reasonable doubt to have been caused by the sparking of an electrical signalling bell, which ignited an accumulation of gas, resulting from a derangement of the ventilation due to the breakage of air pipes. It was afterwards proved experimentally that sparks from the bell in question, worked by a battery of 114 volts, would ignite an explosive mixture of lighting gas and air; and the mixture was also ignited by sparks from signalling wires produced by a current of only four volts pressure..."

It will be noted that these tests were made with an explosive mixture of lighting gas and air, which is ignited with much

It will be noted that these tests were made with an explosive mixture of lighting gas and air, which is ignited with much lower currents than pit gas. The second test at 4-volts pressure was made with an accumulator, which, owing to its low internal resistance, gave a current (not measured) quite disproportionate to that used for signalling purposes.

Following the explosion at the Senghenydd Colliery in October, 1913, a series of tests were made by the Home Office officials in January, 1914, at the New Tredegar Rescue Station, South Wales, at which the author was present representing the colliery owners. The signalling system in use at Senghenydd had been erected prior to June, 1911 (when the maximum pressure allowed in signalling circuits was 15 volts).

henydd had been erected prior to June, 1911 (when the maximum pressure allowed in signalling circuits was 15 volts). The number of dry cells in use on the signalling circuits at the time of the explosion in no material case exceeded nine.

As H.M. Chief Inspector of Mines was not satisfied that these tests were sufficiently exhaustive to settle the safe limit, further tests were made at his request by Dr. Wheeler, at which the colliery owners were not represented. From these tests Dr. Wheeler deduced "That if the current flowing round the signalling circuit could be reduced below 0.30 of an ampere by introducing suitable non-inductive resistances there would by introducing suitable non-inductive resistances there would be little risk of ignition by break flash below 25 volts pressure. The use of Leclanché cells, therefore, owing to their high internal resistance, should afford greater comparative safety than the use of dry batteries."

All these tests show that the principal danger point is the signalling wires, which are usually bare galvanised iron wire, the lead and return wires being run on insulators, signals being

given from any desired point by pressing the wires together or by connecting them by metal bar, file, or knife.

Fig. 11 shows oscillograph records recently obtained at Faraday House across the contacts of bells connected to six "Dania" dry cells, in series with a resistance of 10 ohms, to show the

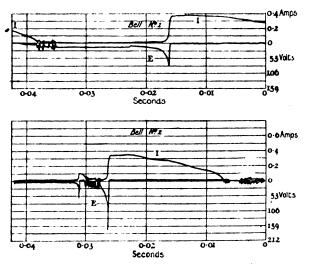

FIG. 11.—OSCILLOGRAPH RECORDS ACROSS BELL TERMINALA.

maximum pressure across bell contacts at the moment of

breaking and making the circuit.

With a cell pressure of 9 volts on open circuit, a momentary pressure of 80 volts was reached with bell No. (1), while bell No. (2), which has the higher inductance, gave a momentary pressure of about 180 volts.

These records show the necessity of considering the inductance of any circuit before specifying the safety limit in terms

of volts and amperes.

There are several alternative systems for securing safety.
Where the distance of signalling is moderate the following system ensures safety:

(1) Bare galvanised wires of No. 8 S.W.G. should be run high up on insulators on opposite sides of the roadway.

(2) Bells to have the contact-maker completely enclosed in

a metal flame-tight cover, the contact being shunted by a resistance or a condenser, the shunt being inside the bell case.

(3) The number of dry cells to be limited to 10 (i.e., 15 volts, as in the Regulations of 1905), the batteries being sub-divided into two groups, one half being placed at either end of the

(4) The batteries to be kept in locked boxes of only sufficient size to hold the standard number of cells, so that they must be replaced when run down instead of an indefinite number being added.

(5) Signals to be made by switches actuated by a "pull" wire, the switches being enclosed in rigid metal, the covers being flame-tight, and the switch contacts breaking contact through non-inductive resistances contained in the same metal

case as the switch.

For long-distance signalling, a high-resistance relay with a shunted contact and enclosed in a flame-tight, rigid, metal case should be used, the shunt resistance being inside the relay case. Where this is done the line pressure can be kept down to 6 volts.

Alternatively the alternating-current system should be adopted. This system has the advantage of getting rid of battery maintenance. The transformer pressure should be 15 volts, and the bells should have their coils enclosed in rigid metal.

#### Discussion in London.

Mr. C. H. Merz, in opening the discussion, paper gave an account of the largest electrified colliery syspaper gave an account of the largest electrined collery system in the country; it was a complete and unified system standardised throughout. It should be noted that the work had been done without Parliamentary powers of any kind, and therefore it had made very great progress. He congratulated the author on the successful use of large gas engines,

and considered that he could not have put the position more fairly as far as the power company's supply was concerned; in fairly as far as the power company's supply was concerned; in every case a connection to the power company's supply would pay if only for reserve purposes. There was also an economy in distribution, as it always paid to combine partially loaded circuits. As electrical engineers, they might confidently look forward to the proof that complete electrification of collieries was justified in all cases. The exhaust turbine was a temporary expedient, nothing more; the main steam winder was a represent of the old form of engine improved at the L. R. and by the turbine; but it could not be improved at the L.P. end by the turbine; but it could not be improved in that way at the H.P. end. He thought there was no doubt that the higher pressures and superheats in use would tend more and more to prime movers independent of the machines to be driven. to prime movers independent of the machines to be driven. It was unfortunate that the author's periodicity differed from that of the South Wales Power Co. If one were to go to the largest possible units the steam cycle would give an efficiency as good as the gas engine. He suggested that the Institution might put it to the author, whether he thought the regulations as to earth plates should be altered and how. With an electric winder on a power company's system it was not as a rule necessary to use the Ilgner set for equalising purposes, and he asked whether the set was really necessary for safety.

Mr. Sydney Evershed said the common system of two bare wires for bell signalling was too useful to be given up because

wires for bell signalling was too useful to be given up because suspicion had been cast on it. There was no real connec-tion between the voltage of the battery and the danger point, tion between the voltage of the battery and the danger point, and greater danger might arise from artificially blowing out the spark than letting it die out, owing to volatilised metal being blown off. He differentiated between a spark which, owing to cooling conditions present, would not produce an explosion, and a flash, which would do so. There was at his own works a piece of apparatus which had been running for months at a time breaking circuits, and a microscope gave no indication of sparking; it was quite possible to obtain sparkless operation. It would be safer to use copper, or coppercoated steel signal wires instead of iron wires, as there would be less sparking; zinc and iron were bad in this respect. Watertight bells were used in the navy successfully, with the hammer action outside.

Watertight bells were used in the navy successfully, with the hammer action outside.

Mr. W. J. LARKE said the author had made a strong plea for the earthed neutral; it should be compulsory, as the perfection of the apparatus now used made such a system quite satisfactory. He thought the advantages of power factor correction were not really appreciated, as for 7s. or 8s. per K.V.A. connected, the correction would be applied over the whole system. He would have thought the squirrel cage motor preferable to the slip-ring type for small surface work.

Mr. HOLLIDAY, referring to the earth plate tests mentioned in the paper, said they had found that brown London clay had the least resistance of any earth. It would appear safe to allow a current density of 25 amp. per square foot of surface for 5 min. or 6 amp. for 3 hours. The earth resistance was much lowered by the presence of soluble salts. They had found it difficult to obtain an independent earth to measure from.

Mr. Rushton said published figures did not show that the Mr. Rushton said published figures did not show that the electric winder had any great advantage over the steam winder, and to obtain the desired result it would be necessary to use the simplest system of winding and a cheap supply, which must be a bulk supply. Using induction motor winders, the peaks would not appreciably affect the power station; even if there were only two winders it would be possible to arrange for the acceleration of one to meet the retardation of the other. Equalising was expensive and should be avoided as far as possible. If numerous earth plates were used, the earth current would be distributed and there would be smaller potential differences.

Mr. Sparks, in replying, said the gas engines had been at

De smaller potential differences.

Mr. Sparks, in replying, said the gas engines had been at work six or seven years and were very successful. The present mining regulations were ahead of anything in force in other countries, but there was still room for improvement. As regarded the Senghenydd disaster, while the electric bell signalling was suspected, there was a lamp chamber in the pit with naked flames in use.

#### DIESEL ENGINE BREAKDOWNS.

Mr. Percy Still, the acting Hon. Secretary of the Diesel Engine Users' Association, has sent us further particulars of the breakdown of a Carels Diesel engine at Oxford on September 26th last year. The engine was a three-cylinder 650-B.H.P. engine running at 240 R.P.M., but as it failed to give the guaranteed fuel consumption, it was reduced to 520 B.H.P. when running at 214 R.P.M. It was built by Messrs. Carels Frères for the Diesel Engine Co., Ltd. The breakdown occurred suddenly, without any intimation of anything being wrong. The big end of the connecting rod of the middle line was found in pieces, some parts being jammed between the crank webs and the bed plate. The connecting rod, complete with its small end and gudgeon pin, was kicked through the side of the frame supporting the cylinder and lay on the floor in a bent condition; the piston was badly smashed, and was in a bent condition; the piston was badly smashed, and was fixed just below the cylinder; the cylinder liner and part of the base of the cylinder casing was smashed, and a portion of the bed plate at the middle line of the engine had been carried away by the blow of the connecting rod. The two outer lines of the engine were intact, and the crank shaft, although it had received several blows, was found to be still true. The fuel valve casing of the middle line was also cracked right through through

fuel valve casing of the middle line was also cracked-right through.

Mr. Philip H. Smith (of Messrs. Smith & Johnson) was called in as a Diesel engine expert to make an inspection and to report on the cause of the breakdown. He arrived at the conclusion that this was due to the failure of one of the bolts in the big end of the connecting rod, which he considered to be of insufficient strength for its purpose. The bolt failed at the neck just under the head, and the metal at the fracture had a crystalline appearance.

Mr. Philip Smith was invited to a meeting of the Diesel Engine Users' Association at which this breakdown was discussed, and there produced tables of figures relating to the stresses in the connecting-rod bolts of various Diesel engines. From these it appears that the Oxford bolts were stressed far too high; they were 2.35 in. in diameter, and bore a maximum stress of 7,000 lb. per sq. in.

Messrs, Willans & Robinson allow a stress of 3,750 lb. per sq. in., and on the assumption that the Willans bolt is "safe," the conclusion arrived at by Mr. Smith is that the Oxford bolt should be \$\frac{1}{2}\$ in. larger in diameter. The Willans bolt has been taken as standard, as it has been found in practice that it takes a violent seizure to make a Willans bolt fail, i.e., stretch or actually fracture. On the basis of the Sulzer stress of 3,000 lb. per sq. in., it appears that the Oxford bolts should have been over 1\frac{1}{2}\$ in. larger in diameter, or about 3\frac{1}{2}\$ in.

The question of the metal forming the bolts was discussed.

bolts should have been over 12 in. larger in diameter, of about 31 in.

The question of the metal forming the bolts was discussed. The Oxford bolt was of iron, the Willans and Carels bolts are of Siemens-Martin steel, and the Sulzer bolts are of crucible steel. Thus, not only were the Oxford bolts stressed higher than others, but they possessed the weakest material. Iron breaks at 24 tons per sq. in., Siemens-Martin steel at 28 to 32 tons, and crucible steel at 34 to 38 tons; hence the factors of safety are 7.7 in the case of Oxford, 18 for Willans, and 27 for Sulzer.

Sulzer.

Sulzer.

As regards the value of annealing, Mr. Smith expressed strong views against it, more particularly in reference to high tensile steels. He expressed his preference for crucible steel bolts, and recommended that big-end bolts be replaced after about 3,000 hours. The precise time would depend on the working stress of the bolts and upon the personal element; a man who permits the brasses to knock, indirectly causes more rapid deterioration of the bolts than a man who carefully adjusts the brasses immediately they require attention.

Mr. Philip Smith has used an empirical formula for a number of years by which the size of the big-end bolts can be gauged with a minimum of data and calculation. This runs as follows:—

as follows:—
Ascertain the diameter over the threads of a "safe" bolt. Then express this as a percentage of the bore. Take the same percentage of the bore of the engine, the bolts of which are to be compared with the "safe" bolt; multiply this figure by the ratio of the piston speeds, and the result gives the necessary diameter of the bolts of the engine under comparison. To instance a concrete example:—Compare the Oxford bolt with the W. & R. 75 B.H.P.

The W. & R. bolt is 11 per cent. of bore; piston speed is 715 ft. per minute. The Oxford cylinder diameter is 23.6 in, and piston speed is 845 ft. per minute. Diameter of Oxford bolt should be 0.11 × 23.6 (845/715) = 3.07 in.

This rule is sufficiently near for all practical purposes, especially in consideration of the fact that after calculating the average stress mathematically one has to adopt a factor of safety in "good recognised practice" of 18 to 27 to ensure a "safe" bolt.

### AUTOMATIC PROTECTIVE SWITCHGEAR FOR A.C. SYSTEMS.

The paper on this subject by Mr. E. B. Wedmore, which was first read before the Institution of Electrical Engineers on December 10th, 1914, and abstracted in our issue of January 8th, 1915, was discussed by the Scottish Local Section at Edinburgh on the 9th inst.

Mr. Page (Glasgow) argued that with the enormous increase in the output from generating plant which had taken place within the last two or three years the selective protection of feeders and distributors had not kept pace; in the majority of cases that was mainly due to engineers not having at their disposal reliable protective apparatus which they could buy at a reasonable price. Things were getting into better shape now. In Glasgow, until recently they had been satisfied to run with an unearthed neutral; in the majority of cases that enabled them to get through with faults on isolated feeders until the faulty section could be fed from another source. They found, however, that there seemed to be a critical stage in all systems; when, for instance, they in Glasgow reached 50,000 kW. of plant running, things happened which were perfectly sound with only 30,000 kW., and a new view of the situation had been forced upon them. They had now decided Mr. PAGE (Glasgow) argued that with the enormous incre

to earth the neutral, while they hoped by using to a considerable extent core-balancing protection that they would be able to get rid of what were really minor faults to earth without affecting the rest of the supply. They were fortunate in affecting the rest of the supply. They were fortunate in affecting the rest of the supply. They were fortunate in series transformers which were at present supplying the instruments in such a way as to get core-balancing with three transformers. They could use their standard three-pole relaysformers. re faults to ground. The problem of the great majority of supply engineers was that they had to adopt some method of supply engineers was that they had to adopt some method of supply engineers was that they had to stop system usually they would have two or three feeders in parallel from the main generating station to the first sub-station, and from thence ring-mains or other system to the bus-bars of the substation further on. If they were going to get through on relays upon such settings the system must obviously be designed to stand up to it and the fine settings were not of any great value. Where a supply was given to sub-stations beyond the first sub-station bus-bar or on a ring-main, balanced core protection was quite useless; if they had an earth, say, upon these ring-mains beyond the sub-station, it was not selective. They would bring out feeders at the power end, which was the very thing they did not want to do. So far as the use of fixed time relays was concerned, it seemed to him that no engineer in considering the protection problem would achieve the protective for being any strength

initially faults to ground. It seemed that Mr. Wedmore ought to have included something else to take care of shorts between phases.

Mr. D. Macfarlane Macleon said that in his opinion the failures which occurred on an extra-high-tension three-phase system, particularly those of higher voltage, took their origin in protective devices. Of course, there seemed to be a limit to the pressures, which he would conclude at 5,000 or 6,000 volts, at which one might expect a quite satisfactory performance, and when one went beyond that there seemed to be a distinct effect upon the protection transformer windings, and the result was that in the course of time instead of avoiding trouble they really caused it. If one were to take into account the failures of supply arising from series transformers one could prepare a formidable indictment against some protective devices, and make out a good case for others. The remedy seemed to be to concentrate the designers' attention on the improvement of these devices. With regard to the use of core-balancing devices, it seemed to him that these devices would remain inoperative in the event of a fault developing upon a sub-station bus-bar or upon any apparatus directly connected with the bus-bars. That was one of the limitations of the core-balancing system, and, indeed, of all protective systems, and they must resort to overload relays in instalments at the power station.

Mr. Newington suggested that though insulation had improved they were not much further advanced than they were in the days of shellacked tape. One felt that had all the brain-power now devoted to electrical devices been put into methods of improving or finding out some new form of insulation these protective devices might not have been necessary.

Mr. Seddon pointed out that while the circulating-current system shown in the paper was an advance as regarded cer-

lation these protective devices might not have been necessary.

Mr. Seddon pointed out that while the circulating-current system shown in the paper was an advance as regarded certainty of action over older methods, it did not isolate the generator in case of failure of excitation as did the reverse-current relay. Perhaps some form of relay energised by the exciter could be used to hold in one of the current-transformer connections. The author had described some ingenious methods of protecting parallel feeders, but he would ask method of protection relays, what happened when one of the parallel feeders had to be switched out of service? It would seem that the remaining feeder would be cut out automatically as there would be no pressure on the restraining coil.

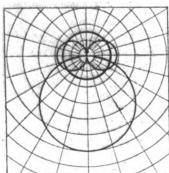

Mr. Wedmore, in his reply, explained that if the neutral point system was installed and one of the phases broke down to earth through the air they got an arc which had all the characteristics of the arc with capacity and shunt, and by its introduction in the circuit they got the well-known humming which Mr. Duddell had explained to them. That humming set up high-frequency and dangerous disturbances in the system which were liable to cause static troubles in unexpected quarters. They did not know enough yet of the metallic arc to know how to put resistance to earth. On the points raised by Mr. Page, when the auxiliary switch had been used, for

example, to cut in in time with a phase in the shunt operating coil, thus making the relay automatically into a straightforward time limit overload relay, they could use the switch to get the relay out of circuit. That was to say, one relay operating, the other relay was cut off circuit and converted into a relay of a different type, and was again automatic and operated correctly, whether the cut-out feeder had no faults or was cut out by hand without disturbing balance protection. There was another way to do this on the auxiliary switch by introducing a setting above what each feeder was expected introducing a setting above what each feeder was expected by the overload relay. If one of the feeders was cut out, they must make use of some of the existing well-known methods of protection. As to transformers, the protective systems advocated were for new work and could generally be carried out with transformers with a single-turn primary which admitted of better insulation than a transformer having a primary winding. He thought there was little reason to fear trouble with the sub-protective transformers as required for the split conductor system. At any rate, the results given so far with the apparatus had been successful, especially as the apparatus had to be regarded as in the development stage.

## THE PRACTICAL RATING OF ELECTRIC INCANDESCENT LAMPS.

THE question whether filament lamps should be rated by wattage or candle-power formed the subject of discussion by the ILLUMINATING ENGINEERING Society on March 16th last, when Mr. F. W. WILLOX put forward claims in favour of rating by wattage and most of the subsequent speakers favoured candle-power rating.

In opening the discussion, Mr. WILLOX said that candle-power as a practical lighting unit was being displaced largely pay as result of its own deficiencies. Rating by candle-power was liable to abuse and had been abused, particularly in the case of lamps with very irregular polar distribution curves. Size rating of filament lamps by total watts had forced itself into practical use as being a simple definite rating which could not be manipulated as candle-power had been. The wattrating had been used in the States and in Great Britain for four or five years past without any serious objection or any practical difficulty. There had been and would be notomplete abandonment of the candle-power unit. Total wattage had simply been adopted as a practical size rating, the watts remaining fixed and candle-power values changing as lamp efficiencies improved. The general trend of practice was towards higher lighting values, and this was ensured by rating on a fixed watt basis. Candle-power values would still be used as needed, but they would be derived values obtained by dividing the watt rating by the efficiency. The majority of lamps were employed on public supply circuits where a definite value in lamp wattage was required by the station engineer and consumer for estimating and checking the consumers of estimating and checking the station area of a room this figure multiplied haves and a total watts basis, which simplified matters greatly. Having measured the floor area of a room this figure multiplied haves engineer and consumer for estimating and checking the cost of service. Practical illumination determinations and estimates were now calculated almost universally on a total watts basis, which simplified matters greatly. Having measured the floor area of a room, this figure multiplied by a constant, representing watts per square foot required to give the desired illumination, gave the total watts required; the actual requirements were determined without reference to candle-power. With candle-power as the fixed primary rating, the wattage of lamps would have to be varied as improved efficiency was attained, and this would introduce manufacturing complexities and confusion for the consumer and supply engineer. In the case of tungsten lamps, for instance, efficiencies had advanced from 1.25 to 1.0 watts per c.p. during the last two years, and if manufacturers had held to fixed c.p. and had lowered wattage as efficiency increased, we should now have the original watt scale over again, but with lamps increased 20 per cent. in candle-power for given wattage. In the meantime there would have been confusion and complexity, and the course which had been adopted, viz., keeping watts constant, was preferable to changing watts and periodically arriving back at the same watt values. With fixed c.p. rating it was necessary, owing to the lower efficiency of 200-250-volt lamps, to have two sets of watt values, one for 100-130 volts and another higher set for 200-260 volts. This would call attention to the lower efficiency of the high-voltage lamps and would lead to complaints from central-station engineers who had to use a 25 or 35-w. lamp whilst a neighbouring station was able to offer a 20 or 30-w. lamp. The Committee on Nomenclature and Standards of the American Illuminating Engineering Society had defined the luminous flux of a lamp as radiant power evaluated according to its capacity to produce the sensation of light. Radiant power was expressed in watts and the evaluating (efficiency) factor was a simple number. It was no the most desirable unit. The fundamental requirement was a definite unit which should always mean one definite thing. This the lumen was and the candle-power was not. Watts per lumen or lumens per watt was perfectly definite, but "watts per candle" at once raised the question as to whether maximum c.r., mean horizontal, mean spherical or mean hemispherical (upper or lower) candle-power were meant. The latitude allowed by the expression "candle-power" permitted and encouraged militarpresentation in lamps, but the lumen could not be manipulated and the lumens output of a lamp remained the same whatever the shape of filament and independent of the reflectors, etc., used, except as regards alsorption losses in accessories. There could be desired no more striking illustration of the confusion possible, under a candle-power rating, than the accompanying geometrical diagram, which represented the same total flux of light (i.e., The fundamental requirement was the most desirable unit.

IDEAL CURVES SHOWING SAME TOTAL LIGHT FLUX IN VARIOUS FORMS OF LIGHT DISTRIBUTION.

the same lumens) emitted in different directions and giving the same lumens) emitted in different directions and giving very different ratings on any other basis than mean spherical candle-power. The output in lumens was simply 4 * × M.S.C.P., and a lumen was easier to think and speak about than a mean spherical candle-power. Flux of light expressed in lumens seemed to be the only unit suitable for expressing the luminous value of modern lamp and reflector or diffusor combinations, which differed so enormously in the distribution they provided from any given lamp. Finally, the lumen was a very convenient unit in practical illumination calculations.

was a very convenient unit in practical illumination calculations.

Mr. C. H. Wordingham said that his views as now expressed on this controversy, which appeared to have reached a deadlock, were from the commercial, scientific and general point of view, uninfluenced by the exigencies of a Government Department which often compelled a narrow view to be taken. The problem had to be considered from three points of view, those of the manufacturer, the central station engineer, and the public. Collectively manufacturers were in favour of watt rating, but individually they seemed to care little about the matter. Central-station engineers took the narrowest view possible and feared that they would be handicapped in their competition with other illuminants if they specified the candle-power of lamps; by working on a watt basis they mystified the consumer and hoped to keep bills constant as the efficiency of lamps improved. Actually, it was essential to compete with other illuminants in price and the lower the price could be brought, the more extensively would electric light be used. The public wanted a certain amount of light and to pay as little as possible for it. Distinction must be made between rating and marking. It was insufficient merely to mark lamps in candle-power. They must be made in a series of even candle-powers, not in a series of even wattages. In his opinion all Mr. Willcox's arguments in favour of watt rating told in the opposite direction and the strongest argument against watt rating was the arguments in favour of watt rating told in the opposite direction, and the strongest argument against watt rating was the fact that lamps of given wattage were of different candle-powers according to their voltage. To rate a radiator by watts input was all right, because the whole input was converted to heat, but to rate a motor or a lamp by input was absurd, because the efficiency was variable. The American Nomenclature Committee's definition, which could be applied to measuring light in watts, referred to watts output, not input. Without photometry it was impossible to tell what a lamp was doing, and both watts input and candle-power output in every direction were necessary particulars.

Prof. S. P. Thompson (communicated): Lamps should be marked in volts, watts and, if desired, spherical candle-power. A standard of watts should be raised since wattage could be verified more easily than M.S.C.P. and wattage was more nearly constant than candle-power during the life of the lamp. arguments in favour of watt rating told in the opposite direc-

lamp.

Mr. A. P. Trotter (communicated): Mean horizontal candle-power had no significance in such lighting units as the "Downlight" lamp. The lumen was not a commercial lighting unit and "lumens per watt" was a method of expression for experts, not for the public.

Mr. T. W. Goodenough (communicated): An actual, not a nominal, rating was required. A buyer with no photometer had to depend on the commercial honesty of the lamp seller, which was often very different from his personal honesty. Since the ratio of input to output was not constant, lamps should be rated and marked in power consumption and candle-power: neither item of information was sufficient without the

other. If the meaning attached to candle-power were standardised there would be no need to use the lumen. Polar curves were necessary for use by illuminating engineers and foot-candles on the working plane was a good basis for illumination specifications, subject to a guarantee as to power

foot-candles on the working plane was a good basis for illumination specifications, subject to a guarantee as to power consumption.

Mr. H. T. Harrison (communicated): To rate in anything but light units was illogical since the light obtained by given power consumption depended entirely on the lamp efficiency. A light-giving rating accurate within 5 or 7 per cent. was near enough for practical purposes. Candle-power had become fixed in people's minds as a measure of light-giving power, and was preferable to the term lumen, so long as the direction of measurement was indicated by symbols. Interior lighting should be specified by foot-candles; it was ridiculous to specify it by watts per sq. ft.

Mr. C. C. Paterson said that rating should certainly be by output since this was what mattered to the user. Further, watts applied only to electric lamps, and the Illuminating Engineering Society should seek a rating equally applicable to all lamps. Changes in efficiency and the variable distribution obtainable from different fittings introduced some difficulty in deciding between flux and candle-power bases, but rating should certainly becon the basis of light-giving power. M.S.C.P. or lumens had a definite reduction factor to candle-power in any particular direction, and could therefore applied easily to illumination calculations. For the present, requirements would seem to be met by standardising existing c.r. bases. Ordinary glow lamps and upright gas mantles should be rated in mean horizontal candle-power and street lighing units in mean lower hemispherical candle-power. The vital point, however, was to rate in light-giving power and not on output. vital point, however, was to rate in light-giving power and not

on output.
Prof. J. T. Morris considered both watts and candle-power

Prof. J. T. Morris considered both watts and candle-power should be marked on every lamp since the user was interested in both factors. Rating should be on output and not on input. It would be worth manufacturers' while to supply polar curves for each type of lamp and for the lamp with the fitting they considered most suitable. They should also give the illumination on a horizontal surface at two distances below the lamp, the distances depending on the use to be made of the lanp.

Mr. McIntyre favoured rating by candle-power, and thought that if the light output of a lamp had not been difficult to measure the watt rating would never have been proposed. Manufacturing convenience might be increased by watt-rating, but the user needed a c.r.-rating and would call for it when the present simple equivalence between watts and c.r. no longer existed. Central station engineers should surely be credited with intelligence sufficient to handle their business equally well whether consumers' lamps were rated by watts or candle-power. The lumen-second was a useful unit representing a definite quantity of light. In addition to the polar curve of candle-power, he had found it useful in comparing various lamps, to prepare a curve showing illumination in a horizontal plane 5 or 10 ft. in diameter, 5 ft. below the lamp. In libraries or other rooms with obstructing furniture it was necessary to specify individual lamps in individual places.

Mr. Fletcher said that most of the previous speakers seemed to think that it was proposed to specify only the wattage of lamps. There was no such suggestion. Watts, watts per c.r., and candle-power were all given in standard lists, and generally polar curves were given as well. Makers were quite prepared to stamp candle-power values on lamps, and he,

and candie-power were all given in standard lists, and generally polar curves were given as well. Makers were quite prepared to stainp candle-power values on lamps, and he personally, was quite prepared to accept any standard system of having lamps tested on a uniform basis by the National Physical Laboratory as suggested by Mr. Gaster.

Mr. T. E. RITCHIE said he would be very sorry to see any more extensive use of watt rating than at present. Watt rating led to absurd and misleading results in arc lamp practice. For all lamps, and particularly where the distribution

rating fed to absurd and insteading results in are lamp practice. For all lamps, and particularly where the distribution curve was unusual, he favoured rating in candle-power (M.H.S. upper or lower with reduction factor for M.S.C.P.) and the provision of the polar curve. Using the lumen as unit eliminated any confusion as to the precise candle-power designation intended, and did not lend itself to inadvertent or other inaccuracies.

Mr. J. G. CLARK showed a number of polar curves to demonstrate the difficulty of rating gas lamps by candle-power. The strate the difficulty of rating gas lamps by candle-power. The polar curve and consumption data were necessary and sufficient to express completely the power of the lamp. There being no equivalent to the watt in gas parlance, he suggested the term cubour (1 cu. ft. per hour), which might also be called a murdoch (after Murdoch, the originator of gas lighting). [Following this suggestion, a representative of the paraffin lamp industry proposed for the latter the unit pint-day to be called a rockefeller!] Mr. Clark considered it desirable that architects should specify interior lighting in foot candles.

Mr. Foulds could see no reason for the present controversy, both watts and candle-power being factors which it

troversy, both watts and candle-power being factors which it was necessary to specify.

Mr. LE MARECHAL admitted that there were advantages in making lamps to a watt rating, but if desired makers were willing to mark both watts and candle-power on lamps.

Mr. MULLARD maintained that as users were accustomed to candle-power rating, it would be confusing and undesirable to try to convert them to the use of watts and lumens.

Mr. Stroud said that whatever the rating it should be accurate. The hefner should at any rate be discarded. Since

some sort of shade had to be used, which quite altered the distribution of light from the lamp, it seemed to him that consumption (i.e., watts input) and efficiency in watts per M.S.C.P. were the particulars which should be specified and form the basis of rating.

Mr. F. S. Tilley urged the necessity for uniformity in the method of judging the performance of lamps, whatever that method might be. Standardised rules were needed and should have a standard to get the standard to get the standard to get the standard to get the standard to get the standard to get the standard to get the standard to get the standard to get the standard to get the standard to get the standard to get the standard to get the standard to get the standard to get the standard to get the standard to get the standard to get the standard to get the standard to get the standard to get the standard to get the standard to get the standard to get the standard to get the standard to get the standard to get the standard to get the standard to get the standard to get the standard to get the standard to get the standard to get the standard to get the standard to get the standard to get the standard to get the standard to get the standard to get the standard to get the standard to get the standard to get the standard to get the standard to get the standard to get the standard to get the standard to get the standard to get the standard to get the standard to get the standard to get the standard to get the standard to get the standard to get the standard to get the standard to get the standard to get the standard to get the standard to get the standard to get the standard to get the standard to get the standard to get the standard to get the standard to get the standard to get the standard to get the standard to get the standard to get the standard to get the standard to get the standard to get the standard to get the standard to get the standard to get the standard to get the standard to get the standard to get the standard to get the standard to get the standard to get the standard to get the standard to get the standard to get the standard to get the standard to get the standard to get the standard to get the standard to get the standard to get the standard to get the standard to get the standard to get the sta

method of judging the performance of lamps, whatever that method might be. Standardised rules were needed and should be adopted universally. At present it was impossible to get uniform results from tests by different people.

Mr. J. S. Dow said that for a general scientific comparison Mr. J. S. Dow said that for a general scientific comparison of the candle-power in all directions, whether measuring it as M.S.C.P. or lumens. This was imperative since almost any desired polar curve could now be obtained by use of suitable reflectors. The illuminating engineer must have the polar curve in every case, and it was interesting to note that practically every manufacturer now included polar curves in his lists, whereas five years ago they hardly knew the meaning of such curves. Given a calibrated polar curve for every lamp and reflector unit, it was an easy matter to predetermine and ensure obtaining desired illumination. To prevent the use of fittings which directed all the light on to the working plane, to the detriment of general lighting, interior illumination should be specified by illumination on the working plane and a certain M.S.C.P. or lumens for given cubical space.

Mr. L. Gaster said that any legislation in lighting matters and any accurate predetermination of results depended on realighly makers' deta.

Mr. L. Gaster said that any legislation in lighting matters and any accurate predetermination of results depended on reliable makers' data on a uniform basis. This could be obtained by standard tests by such a body as the National Physical Laboratory, and makers should be entitled to claim that some, at any rate, of the tests be carried out under conditions specified by them, so that indisputable evidence would be available as to the capabilities of lamps in the special applications for which they were intended.

In reply. Mr. F. W. Willicox said that the views put forward that evening had been advanced in America several years ago and had been refuted by practical experience. The crux of the matter was whether watts or candle-power should be fixed, and practical experience and evolution had shown watt rating to be convenient and acceptable.

#### HIRING POWERS FOR COOKING APPLIANCES.

In sending us the following extract from the Minutes of the Glasgow Electricity Committee, Mr. H. FARADAY PROCTOR, Hon. Secretary of the I.M.E.A., points out that the terms accepted by the Scottish Contractors' Association are less favourable to them than those embodied in the I.M.E.A. Bill. The report of the special sub-committee on hiring of cooking appliances, etc., from which the extract is made, was dated March 4th, 1915, and states that as the result of a conference with a sub-committee of the Electrical Contractors' Association of Scotland (Glasgow Branch) as to the establishment of a central show-room in the city, with the following objects in view: (a) to provide facilities for present and prospective users of electrical energy; (b) to exhibit a selection of the latest electrical appliances in one place instead of having to visit numerous places scattered over the city; (c) to promote latest electrical appliances in one place instead of having to visit numerous places scattered over the city; (c) to promote the use of electrical appliances for lighting, heating, cooking, etc.; and (d) to educate the public with regard to the possibilities of these appliances—the electrical contractors had now agreed that the proposed show-room should be equipped and managed entirely by the Corporation for five years from the date of opening the same, on the following lines:—

That the show-room shall exist primarily for the exhibition of electrical appliances:

of electrical appliances;

That the contractors and their customers shall be afforded all possible facilities for inspecting the stock of appliances

all possible facilities for inspecting the stock of appliances kept in the central show-room;
That any electrical contractor who shall request the Corporation to sell from the stock in the central show-room any fittings, accessories, lamps, or apparatus shall be entitled to receive out of the purchase price one-half of the discount which he would have received from the makers, had the contractor

rom the show-room shall be at list prices, such list prices to be the usual current list price of the firm supplying goods to

the show-room;
That, as far as possible, sales initiated in the show-room shall be completed through the contractor who directed or sent the customer to the show-room;
That all wiring work resulting from inquiries at the show-room-shall be done direct by a contractor, and no undue preference shall be shown to any one or more electrical con-

That the hiring of apparatus shall not be undertaken from the show-room, but the show-room management shall be free to lend apparatus for a short period to possible customers under exceptional circumstances, and make a charge, if they think fit, for the loan of such apparatus; and

That all charges made to consumers by the show-room management shall be separately stated on the relative demand notes sent to consumers, and all sums paid to and obtained by the Corporation as a result of business done in the show-room shall be separately shown in the annual accounts of the Corporation Electricity Department, which accounts are audited by an independent auditor.

## FOREIGN AND COLONIAL TARIFFS ON ELECTRICAL GOODS.

CANADA.—With reference to the notice published in a recent issue of the ELECTRICAL REVIEW calling attention to a revision of the Canadian Tariff, the Board of Trade notify that they have now received the full text of the Resolution of the Canadian Parliament, having effect from February 12th. By this resolution it was provided that in addition to the customeduties formerly levied additional duties of 5 per cent. under the British Preferential Tariff, and 7½ per cent. under the Intermediate Tariff and General Tariff should be imposed. These duties will also be levied on goods formerly free of duty, with certain exceptions, which include advertising and printed matter imported by mail; locomotives and passenger and matter imported by mail; locomotives and passenger and goods wagons; models and inventions; scientific apparatus, utensils and instruments.

the effect of this alteration in the Canadian Tariff will therefore be to increase by 2½ per cent. ad valorem the amount of the preference formerly granted to British goods.

The Board of Trade have received a communication from H.M. Trade Commissioner in Canada drawing attention to the regulations respecting the importation of samplesvia the United States into that Dominion. H.M. Trade Commissioner states that if samples have not been used in the United States for the purpose of securing trade, but are brought into the Dominion direct from the United Kingdom via the United States, duty will be collected thereon at the Canadian port of entry, and the amount collected will be refunded if the samples are exported again within a period of twelve months after the date of entry. If, however, the samples have been used in the United States for the purpose of securing trade, duty will be collected thereon and cannot be refunded when the samples are re-exported.

NORTHERN RHODESIA.—A proclamation recently issued

refunded when the samples are re-exported.

NORTHERN RHODESIA.—A proclamation recently issued by the Northern Rhodesia Customs Authorities states that in future duty levied ad valorem on imported goods will be assessed on the true current value of the goods when sold for home consumption in the open market in the principal markets of the country from which, and at the time when, the goods were exported, including carriage to the port of shipment and the cost of packing and packages, but not including agents commission when such commission does not exceed five per cent., provided that in no case shall the value for purposes of assessing duty be less than the cost of the goods to the importer at the port of shipment. the port of shipment.

COSTA RICA.-A Presidential Decree recently issued provides for a surcharge of two per cent. on the duties on all imported goods, to be levied from February 1st. Goods imported for consumption in the Province of Lima will, however, be exempt from this surcharge as they are already subject to a similar surtax imposed by a previous decree.

BRITISH COLONIES AND PROTECTORATES.—Regarding the proposed application of the United Kingdom rules respecting the requirement of certificates of origin for various goods shipped from certain neutral European countries to the goods shipped from certain neutral European countries to the various British Colonies not possessing responsible Government and the Protectorates, the Board of Trade have now been informed by the Foreign Office that goods shipped from such countries to any British Colony or Protectorate on or after March 15th last must be accompanied by a certificate of origin exactly as if they were being shipped to the United Kingdom. No certificates are, however, at present required in ordinary circumstances in the case of goods shipped to Egypt. It may be stated that regulations have already been adopted regarding the requirement of certificates of origin in the case of goods shipped to British India, Australia, New Zealand and South Africa, but similar certificates are not at present required for imports into the Dominion of Canada and Newfoundland. This is, of course, irrespective of the ordinary certificates of origin required for British goods to secure entry under the Preferential Tariff.

SOUTH AFRICA.—The Board of Trade have received from H.M. Trade Commissioner in South Africa information as

H.M. Trade Commissioner in South Africa information as to a revision of the South African tariff. In addition to certo a revision of the South African tariff. In addition to certain alterations in the duties on specific goods not of interest to the electrical trade it has been decided to increase the general rate on goods not specially mentioned in the tariff from 15 per cent. ad valorem to 20 per cent. ad valorem with a rebate of 3 per cent. ad valorem as formerly in the case of goods of British origin. This rate is applicable to a large number of electrical goods. The new duties are payable as from March 5th last.

HOLLAND.—A recent Royal Decree re-imposes the prohibi-HOLLAND.—A recent Royal Decree re-imposes the prohibition of the exportation of nitric acid, which has been suspended since August 23rd last. A further decree withdraws previous decrees relating to the prohibition of the export of copper and copper alloys, and prohibits the export of copper and copper alloys whether as raw material or as manufactures, unless used as part of any manufactured article of which copper or copper alloy does not constitute a main component part. The right to decide whether copper or copper alloy forms a "main component part" of any manufactured article is reserved to the Minister of Finance.

FRANCE.—A Presidential Decree, dated March 3rd, suspends the import duties on rails and fishplates for the repair of ways and communications which are of importance for national defence. This latter condition is to be proved by means of certificates delivered by the Administration des Travaux Publics. A further Decree of the same date suspends, as from March 4th for a period of six months, the import duties on rails and fishplates for tramways up to a total quantity of 5,000 metric tons of rails and 250 metric tons of fishplates. The privilege of duty free admission under the terms of this Decree is contingent upon the production, in the case of each consignment, of a certificate from the local authority attesting that the material imported is actually destined for the installation or repair of tramways.

#### BRITISH ELECTRICAL PATENTS APPLIED FOR OR COMMUNICATED BY RESIDENTS IN GERMANY, AUSTRIA OR HUNGARY.

The following list of British Patents, applied for or communicated by residents in Germany, Austria, and Hungary will be found of interest to manufacturers or others desiring to avail themselves of the provisions for Compulsory Licence under the new Patents Act. Intending licensees should, however, not assume without further enquiry that any patent in the list is not already assigned or licensed, or that the applicant is an "enemy subject."

The list is specially compiled for the ELECTRICAL REVIEW by Messrs. W. P. THOMPSON & Co., 285, High Holborn, W.C., and 6, Lord Street, Liverpool.

#### THE ILFORD RAILWAY COLLISION.

LIEUT-COL. VON DONOP'S report on the collision which occurred on the Great Eastern Railway at Ilford, on the first day of the year, has now been issued, and, as was, perhaps, to be expected from the evidence given at the inquest and from the character of the signalling apparatus in use, the Colonel comes to the conclusion that there can be no doubt the driver did not exercise sufficient care in noting the positions of his signals "when approaching Ilford," and "that it is entirely to this want of care on his part that this collision must be attributed." There are, however, some points arising from the report which are of very considerable interest.

In dealing with the lay-out of the station and signal-boxes at Ilford, Colonel von Donop gives the distance between the East and West boxes as just over 250 yards. This being the case, it would have been thought that passenger trains would have been dealt with under the "400 yards rule," as laid down in the third paragraph of Rule 4 of the Regulations for Train Signalling by Block Telegraph on Double Lines of Railway. This paragraph reads as follows: — "When the home signal at the signal-box in advance is less than 400 yards ahead, permission for a train to approach must not be given to the signal-box in the rear until permission for the train to proceed has been received from the signal-box in advance, except in the case of a train not conveying passengers, which may be accepted under Regulation 5, when the advance section is not occupied by a train conveying passengers."

In his evidence, the signalman on duty at the East box at the time said: "I remember being offered the Clacton train from Ilford carriage-sidings signalbox (from which the Clacton train was approaching) at about 8.37 a.m. I accepted it at once. At the same time I also offered it to the West signal-box. He did not accept it." The procedure seems to have been in this case exactly the reverse of that laid down by the rule quoted. Had the rule been carried out, the signals at the Ilford carriage-sidings signal-box would have been kept against the train, and an additional check against over-running at the critical point would have been interposed. It does not necessarily follow that the driver would have run past the latter signals: from his evidence it appears that he had noticed other signals at danger. since he said in giving his evidence: "after leaving Shenfield we were just checked at Brentwood." A driver is entitled to the protection of all the signals which a due observance of the rules of signalling afford him. In this case it would seem that full protection has hardly been given.

Digitized by Google

The signalman at the East box made no mention in his evidence on January 5th of having received from the West box the blocking-back signal, which the signalman at the latter box said he had sent, but when further examined on February 2nd he remembered the circumstance. What was the object of giving this signal, or what gave rise to the necessity, is not made apparent. That such a signal should be given seems very strange, since it was inapplicable to the conditions and the place. The rule for blocking back says: "Trains or engines approaching a junction on a line converging to a fouling point, or when leaving an independent line, or a siding, to at once proceed on their journey, or crossing directly over another running line are exempted from the operation of blocking back, and must be dealt with under Regulation 4." The blocking-back signal requires permission from the man receiving it before it can be acted upon, and such permission could not be given by the man at the East box, since he had already accepted the Clacton train, and the necessary distance of half a mile between his home signal and that of the box from which the signal was received did not exist. The quotation from the blocking-back regulations shows that that signal was inapplicable to the conditions existing, since the Gidéa Park train was merely crossing from the local to the main line. and was intending to continue its journey at once. The 400 yards rule is obviously intended to prevent the chance of over-running of signals in precisely the circumstances obtaining in the Ilford accident. The inspector summarises the evidence of the two signalmen in question, together with other evidence submitted, but makes no comment with regard to the apparent non-observance of the 400 yards rule quoted, or the effects that might have followed from carrying it out; nor does he remark upon the use of the blocking-back signal by the West box signalman when offered the Clacton train from the East box, or the apparent want of reason for the use of that signal.

Another point brought out by the report is that in advancing from the east towards Ilford Station a train passes first the Ilford East box up-distant signal, and afterwards the up-advance of the box in the rear, i.e., of Ilford carriage-sidings signal-box. Similar arrangements might be found on other lines besides the Great Eastern, and there may be good reasons for them from the traffic-working point of view, but there are none from the point of view of signalling. A driver, when he has passed the distant signal for any section, has the right to consider that all stop signals he meets subsequently will refer to the section covered by the distant, and not to the section behind it. The signalman at Ilford carriagesidings signal-box said that all his signals, including the advance in question, were off for the Clacton train; and the question arises whether this was not the signal which the driver "sighted" as the East box distant and "took it to be off: it was not in a doubtful position." It must not be forgotten that the Ilford East box up-distant was not "repeated" under the Ilford carriage-sidings box advance; that the only difference between the two arms would be

the slot in the end of the distant arm; and that the two signals each occupied the other's position on the line under the usual conditions of erection. must it be forgotten that drivers are acquainted with the rules guiding the signalmen, not, perhaps, to the full extent, but sufficiently to recognise the general conditions applicable to such a case as this, and sufficiently to lead the driver to infer from such knowledge that if all the signals were off for the Ilford carriagesidings box, as was the case, the working of the 400 yards rule would ensure the line being clear to the Aldersbrook box west of Ilford West box. It is not sought by these remarks to minimise the driver's responsibility for the accident. It was undoubtedly his duty to observe and obey the signals, and his own evidence and that of others shows that in the words of the report "the morning on which the accident occurred was a clear one." Nevertheless, as the report shows on examination, there were other circuinstances in connection with the occurrence which might well have been the subject of explanation.

The concluding paragraph of the report deserves special attention. Colonel von Donop draws attention to the desirability of providing "an unmistakable warning" as to the position of a distant when being passed: to the fact that several railway companies have made trials of devices for the purpose, and that on some lines such devices are in use to a limited extent; that the Great Eastern does not come into the category of the lines alluded to, although it has provided around London a large number of emergency detonator machines at its home signals; that it is at the distant signal that the warning is specially needed; and, finally, "in the face of this accident," the company's attention is called to "the

desirability of this provision.

The paragraph seems to lack that directness of statement that one looks for in such reports. One is led to infer from the opening sentences that Col. von Donop refers to cab-signalling as providing something in the way of "an unmistakable warning," and probably it is so, but it is not so stated. The paragraph then refers to the detonator machines at the home signals; states that it is at the distant that the warning is especially needed, and calls the attention of the company to the desirability of this provision. Which? Cab-signals or detonators? It is possible to argue that only cab-signals giving both on and off indications can be meant, for the reason. that detonators only indicate one position, and would not, therefore, meet the conditions, and give a warning showing the (actual) position when being passed, but it should not be necessary to have to revert to such reasoning.

THERE has been a pretty steady tone in Rubber. the market for crude rubber during the past few weeks, and price movements have been of but small importance though the tendency has been quite satisfactory from the point of view of producers, and this, notwithstanding the rather more subdued demand experienced from home trade manufacturers. There has been considerable apprehension entertained in connection with the difficulty of shipping material from Singapore, owing to the exceedingly limited freight facilities (which, by the way, look like being rendered more restricted still), and this may have a by no means unimportant bearing upon the position in a few months' time. Not only so, but there has been very slow progress made with the discharging of steamers arriving at London, and this has necessarily much hampered operations, whilst restricting the supply of parcels available for early delivery. There is no doubt that the demand which was experienced for parcels readily available, contributed substantially to the firmness of the market until towards the middle of the month, but latterly labour conditions at the docks have been slightly improved. the working of the vessels proceeding rather more smoothly, and there seems now to be a more ready supply of spot and ready parcels available for the satisfaction of current needs. This, however, has not had much influence upon the tendency of the market generally. The clearances which have been made for the United States have been well below requirements, but it is hoped that the execution of outstanding orders will make more headway in future, and that at the same time United States demands will undergo an expansion within the next few weeks. Meantime the prospects as regards home consumption during the spring months are regarded as very encouraging, the demands for tires and other material of first-rate importance successful pursuit of the war on the Continent being such as to keep all working forces available employed at the utmost limit of productive capacity.

The efforts which have been made so consistently for two or three years in the direction of bringing down the cost of production of plantation rubber are now beginning to tell, and some of the reports of producing companies issued lately reveal the extent of the progress which has been made in this direction. It is significant, too, that these costs have been reduced, notwithstanding the very great difficulties which had to be faced in connection with the outbreak of war. The reduction in cost per lb. is rather startling in some cases. The Bikam concern, for instance, has dropped its all-in cost 5d. a lb. Selaba is 41d. to the good, Golden Hope 31d., and Pataling 21d. a lb. on the right side compared with 1913, the cost of the last-named company being now actually below 10d. per lb., and these costs also include war risk insurance. The improvement costs also include war risk insurance. does not arise entirely, moreover, from increased production, but is largely due to more efficient management of estates and the determined adoption of more economic conditions.

According to official figures issued, the exports of plantation rubber from the Straits Settlements during February amounted to 2,741 tons, as compared with 2,576 tons in January, and 1,703 tons in the corresponding month last year. The following table gives the comparison month by month for three years:—

	1913.	1914.	1915.
January	784	1,181	2,576 tons
February	743	1,703	2,741 "
Total	1,527	2,884	5,317 ,,

These figures include transhipments of rubber from various places in the neighbourhood of the Straits Settlements, such as Borneo, Java, Sumatra, and the non-Federated Malay States, as well as rubber exported actually from the colony, but they do not include rubber exports from the Federated Malay States.

Artistic Lighting trial age the artistic development of lighting fixtures has frequently fallen far behind their development in efficiency, but even in industrial concerns where economy is rightly given first consideration, it is becoming realised that colour and effect may compensate for some difference in actual cost. Industrially, this applies chiefly to the light itself, but in domestic and public interiors, and in exterior lighting, fixtures play, or should play, an important part in the decorative scheme. There is an artistic as well as a practical aspect of artificial lighting, and now that such efficient luminous sources are available, we can afford to pay attention to effect as well as efficiency.

Antique and medieval lighting fittings were evolved to utilise the crude lighting agencies then available. Though at first as crude as the sources themselves, these fittings were gradually brought to a very high art level, and with the universal adoption of electric lighting, which can be adapted easily and safely to any form of fitting, there is a pronounced tendency to revert to Renaissance styles, Flemish models, and the styles of the seventeenth and

eighteenth century French periods. Is it wise to follow these traditional styles, or ought we to create new and distinctive styles? In a paper before the Illuminating Engineering Society, Mr. F. W. Thorpe showed recently the very pronounced effect of even the earliest lighting devices on modern fixture design, and maintained that in interiors where it is sought to reproduce the atmosphere and spirit of the past, lighting fixtures should be as true to style as the other details of furniture. The inherent characteristics of electric lighting make this possible without risk and without incongruity.

On the other hand, the fittings of the past, particularly candelabra with their wide-spread, low-reaching arms, were evolved to snit dim and feeble sources of light, and attempts to reproduce them for artistic reasons are not facilitated by the relatively high domestic supply pressures and high-efficiency lamps now employed. Art is certainly not a product of modern civilisation, and there is no reason to suppose that in these days it can be carried to a higher level than was attained by the craftsmen of the past. Reproductions of their work, adapted with rigorous conservatism to modern requirements, often make up by their importance in the decorative scheme of an interior for what they lack in efficiency. The latter deficiency can frequently be made good by inconspicuous high-efficiency lighting to which the artistic fittings are supplementary as regards lighting, but predominant in æsthetic effect.

For modern interiors, however, where rigid purity of style is not required, advantage can be taken of the charm of contrast, and there is, no doubt, room for distinctive twentieth-century styles, if these can be evolved as a reasonable compromise between beauty and efficiency. modern fittings-particularly those of foreign origin-bear painful witness to the influence of cheap production on art. At the other extreme—in the production of art fixtures more or less regardless of cost-fittings manufacturers complain that unless they follow rigidly one or other of the fashionable traditional styles in vogue among architects, they can find no market for their products. Co-operation between architect, fittings manufacturer, and illuminating engineer is desirable and practicable. There is no reason why one of these should dictate to, or restrict the initiative or spoil the work of, either of the others. A flagrant example of neglected opportunity is to be found in almost every new building erected for commercial purposes or as a place of entertainment. It is known from the first that electric signs will be erected, but no place is left for them in the architect's scheme. As a result, the sign loses in its own beauty and effect, and only too often constitutes an eyesore by day

In interiors there is room for individuality in the selection of fixtures, and the owner alone is credited with good or bad taste. Public lighting is, however, credited—or more usually debited—to national taste, though it is rarely representative thereof, even in the case of buildings erected by public authorities. There seems to be a tendency to think about lighting at the last moment, when either opportunity or funds available do not permit the provision of illumination worthy of and harmonising with the architectural scheme. As many public buildings are used more by artificial light than by day, this policy is the more inexplicable.

The lighting of streets should, at any rate in times of peace, be first of all efficient. At the same time, there is no reason why the considerable annual expenditure on new lamp-posts should not produce rather more acceptable standards than are generally to be found in our streets. Except in special cases, very ornate and costly designs would be out of place, and it does not seem generally necessary to make special arrangements for the lamp-post to be seen in all its details by night-with many existing designs, darkness is certainly merciful. True art may be quite simple; indeed, many of the lamp-posts now in use would be far more artistic, as well as cheaper, were their "decorations" omitted. Without emulating the extraordinary and often hideous fixtures which provide "display" lighting in the White Ways of the States, there is no reason why we should not use, at the same or less cost than at present, street standards which are effective by night, and, at least, not offensive excrescences by day.

#### ELECTRIC TOWING SYSTEM FOR THE PANAMA CANAL LOCKS.

THE towing system described below was designed and patented by Mr. Edward Schildhauer, electrical and mechanical engineer of the Isthmian Canal Commission; and the 40 towing locomotives and all the electrical apparatus for operating the locks were built by the General Electric Co., of Schenectady, U.S.A. Some particulars of the system have already appeared in our pages.

In passing through the Canal from the Atlantic to the Pacific, a vessel will enter the approach channel in Limon Bay, which extends to Gatun, a distance of about 7 miles. At Gatun it will enter a series of three locks in flight and be raised 85 ft. to the level of Gatun Lake. It may then steam at full speed through the channel in this lake, for a distance of 24 miles, to Bas Obispo, where it will enter the Culebra Cut. It will pass through this cut, which has a length of 9 miles, and reach Pedro Miguel, where it will enter a lock and be lowered 30 ft. Then it will pass

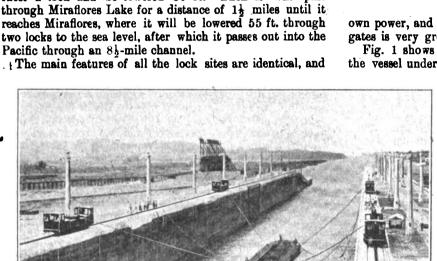

Fig. 1.—Towing Locomotives' First Trial Run with Barge through Gatun Locks,

the Gatun Locks may be taken as a typical example. There are two ship channels, one for traffic in each direction, separated by a centre wall, the total length of which is 6,830 ft. There are two systems of tracks, one for towing and the other for the locomotive returning idle. towing tracks are placed next to the channel, and the system of towing utilises normally not fewer than four locomotives running along the lock walls. Two of them are

opposite each other in advance of the vessel, and two run opposite each other following the vessel, as seen in fig. 1. The number of locomotives is, however, increased when the tonnage of the ship demands it.

Cables extend from the forward locomotives and connect with the port and starboard sides respectively of the vessel near the bow, and other cables connect the rear locomotives with the port and starboard quarters of the vessel. The lengths of the various cables are adjusted by special winding drums on the locomotives to place the vessel substantially in mid-channel. When the leading locomotives are started, towing the vessel, the trailing locomotives follow and keep all the cables taut. By changing the lengths of the rear cables, the vessel can

be guided; and to stop the vessel, all the locomotives are slowed down and stopped, thus bringing the rear locomotives into action to retard the ship. In this way the vessel is always under complete control quite independently of its

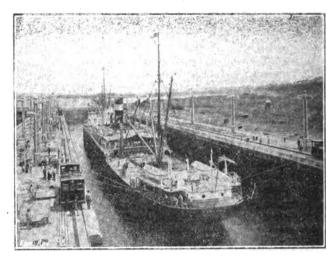

Fig. 2.—S.S. "Ancon" entering Upper Lock, towed by Electric Locomotives,

own power, and the danger of injury to the lock walls and gates is very greatly lessened.

Fig. 1 shows how effectively the four locomotives keep the vessel under control and in the centre of the channel,

while figs. 2 and 4 give a general idea of the method of handling vessels of various sizes. They also show general views of the lock walls, towing tracks

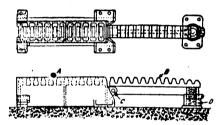

FIG. 3.-APPROACH SECTION OF RACK RAIL.

and the inclines, the steepness of the latter being especially noticeable.

The towing tracks have a specially designed rack rail extending the entire length of the track and located centrally with respect to the running rails. It is

through this that the locomotive exerts the traction necessary for propelling large ships and climbing the steep

A rack rail (A, fig. 3) is also provided on short portions of the return track so as to lower the locomotives safely from one level to the next. The steepest slope is 26°, or 44 per cent., hence the need will be seen for rack rail even on the return track, it being noted that any traction

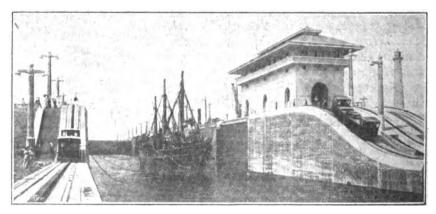

FIG. 4.-U.S. TENDER "SEVERN" AND FIVE SUBMABINES PASSING THROUGH GATUN LOCKS

locomotive with the usual wheel drive, even with the brakes set, would begin to slide on a 16 per cent. grade, and therefore could not be controlled.

A small portion, B, at the end of the rack rail is hinged at

c, so that it can be depressed on the approach of the rack pinion of the locomotive; the teeth of this approach section are under size and shaped off at the extreme end, so that the teeth of the pinion will mesh properly and prevent excessive strain on the pinion and the axle. A spring, D, restores the approach to the proper position after the locomotive has passed over. The rack rail is of the shrouded type, and each tooth space has a drain hole cast in the bottom.

The rack rail also has projecting edges, which permit thrust wheels attached to the locomotive to run along the under side and prevent overturning of the locomotive, in case some unforeseen operating condition should produce an a substantial horisontal platform to support the driving motor, and its outer end is supported at each corner by two springs, placed above and below a stationary angle iron, and connected to the bracket by a bolt, so as to afford a yielding support in both upward and downward movements of the bracket.

The motor is of the three-phase, enclosed slip-ring type, geared by a pinion and spur gear to the countershaft, which carries a pinion meshing with a spur gear, keyed to the jack shaft. On the outer side of the spur gear are formed clutch teeth, which co-operate with similar teeth on the adjacent side of a gear which is sleeved upon the jack

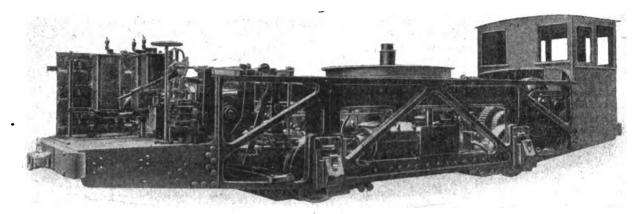

FIG. 5 .- ELECTRIC LOCOMOTIVE, WITH COVERS AND ONE CAB REMOVED, SHOWING CONTROLLERS, &C.

excessive pull on the towline. These thrust wheels serve to counteract the lateral component of the towline pull, and the flanges act for emergency only, as the weight of the locomotive is sufficient to prevent overturning with a normal pull of 25,000 lb. on the towline.

Three-phase, 25-cycle, 22Q-volt alternating current is used for operating the locomotives, and the current is supplied to them through an underground conduit adjacent to the running rail on the side remote from the lock; two T-rails form two legs of the three-phase circuit, and the third leg is formed by the main track rails. A specially-designed contact plough slides between the two conductors and collects the current from the rails.

The working parts of the locomotive are supported by two longitudinal upright side frames of cast-steel, connected by transverse beams; these frames are in effect deep rigid trusses, having upper and lower members connected by posts and diagonal braces. The pedestals for the wheel axles

Fig. 6.—Arrangement of Motor, Gearing and Spring Suspension.

are of the usual locomotive type, having vertical parallel jaws between which the journal slides. Springs are interposed between the tops of the journal boxes and the tops of the pedestals, and the locomotive is thus mounted upon four wheels, the wheel-base being 12 ft., and the overall length of the locomotive over 32 ft.

Each axle is driven by its own motor, independently of the other. A cast-steel suspension bracket is hinged at one end on the axle (fig. 6). The bracket is provided with bearings for a transverse jack shaft, parallel to the axle; and it has pillow blocks for a countershaft, also parallel to the axle. It has

shaft, and can be slid lengthwise thereon to engage and disengage the clutch teeth. A pinion keyed to the main axle is wide enough to mesh always with the gear, so that when the clutch teeth are engaged, the motor will propel the locomotive by the adhesion between the wheels and the rails of the track. The gearing is shown in fig. 7.

When the locomotive reaches one of the inclines between the locks, or when it is towing a ship, the cog rail system is utilised to enable the locomotive to climb the grade and exert the traction necessary. The cog or rack rail is laid between the track rails, and the locomotive is provided with a rack pinion secured to a sleeve which rotates freely on the axle.

A gear wheel secured to this sleeve meshes with a

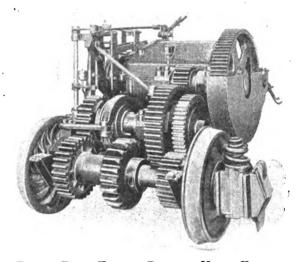

Fig. 7.—Front View of Traction Motor Unit, Clutches and Brake-Gran.

gear turning loosely on the jack shaft. Clutch teeth on this gear can be engaged by the teeth on a clutch which is splined to the jack shaft. A lever, pivoted to a collar riding in a groove in the clutch, is connected by a laminated flat steel spring with a handle in the cab of the locomotive, and is also pivoted to a rod which throws out the former clutch when the latter is thrown in, and vice versâ.

The jaw clutches in most cases do not mesh when thrown, but the operating handle is thrown full stroke and locked. This puts the springs under heavy tension. The locomotive is then started slowly, and when the clutches are

in alignment the springs throw them without any attention by the operator.

by the operator.

The two traction motors are controlled by suitable controllers installed in the cabs at the ends of the locomotives; the circuits are such that both motors can be controlled from either cab, and they can be operated singly or in parallel, as desired.

Each motor, with all its gearing and clutches, is mounted independently of the frame of the locomotive, to which it is connected only by springs, which give an elastic support for the outer end of the bracket, on which the mechanism is

carried, as shown in fig. 6.

In connection with each motor a powerful brake is installed; and as during operation the motors are at all times geared either to the axles or to the cog wheels, the truck wheels are not provided with any brake rigging. On the motor shaft is keyed a brake drum, and to opposite sides thereof are applied the brake shoes, carried by levers pivoted on a stationary bar. The movable core of a solenoid is pivoted to the long arm of a lever, which, with the brake levers, constitutes a sort of toggle. When the core of the solenoid drops, it actuates the mechanism in such a manner as to apply the brake shoes to the drum. The winding of the solenoid is in circuit with the controller of the motors, so that when the current is turned on to energise the motor windings, the solenoid will lift its core and thereby release The first point of the controller raises the brakes without applying power to the motors, thereby providing a coasting point. But should the motor current be shut off, either intentionally or accidentally, the

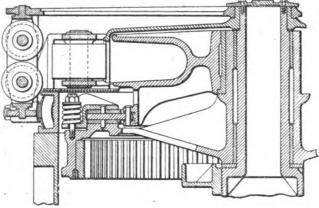

FIG. 8.—PART SECTION OF CABLE GUIDES, DRUM AND FRICTION CLUTCH.

core will instantly drop by gravity, and its weight will exert a powerful leverage upon the brake levers to stop the motor and the locomotive. In addition to this automatic brake, means are provided for applying the brakes manually, in order to supplement the action of the automatic feature, if necessary, when descending a grade or where approaching a rack rail.

The drum on which the cable is wound is located midway between the ends of the locomotive and above the upper member of the side frames, so that the cable can be led off on either side of the machine and through a wide range of angles to the line of travel. The hub of the drum is pivoted to the hub of a spider, which, in turn, rotates upon the upper portion of a massive tubular vertical column rising from a pedestal secured to the baseplate, which is supported on the lower members of the side frames. As shown in section in fig. 8, the spider supports a circular rim with a horizontal upper surface, to which is applied a powerful friction clutch connecting the spider and the drum.

friction clutch connecting the spider and the drum.

Inside the flanged rim of the spider is secured a large internal gear, with which mesh two driving pinions, secured respectively to two upright shafts.

A wormgear is clutched to one of the shafts, and is driven by a worm on the shaft of an electric motor bolted to the base of the locomotive.

A bevel gear is keyed to the other shaft, and meshes with a bevel pinion on the shaft of an electric motor fastened to the base. The latter is used for driving the drum at a high speed when coiling the cable that has been cast off, and it remains permanently in gear. The other motor, with wormgear drive, is used for taking in the cable

when it is under load, and the drum operates as a windlass or capstan. The wormgear drive is disconnected from the drum when not in use, by means of a clutch. The first point of the controller which operates the bevel-geared motor raises the clutch by means of a solenoid, and on the second point the motor starts.

The guide which directs the cable, as it pays out or winds up, is mounted so as to revolve on the axis of the drum. One portion of it is a circular bell which serves as a cover for the winding drum; the hub of the bell is journalled on the upper end of the column, being stepped on a shoulder thereon (fig. 8). At one side the housing is cut away to admit the cable to the drum, and on each side of this opening is bolted one end of a frame carrying two upright guide rolls, which have cylindrical faces.

The other guide member is a radial casting turning freely on the hub of the cover, and carrying at the outer end two grooved sheaves on horizontal axes. The edges of these sheaves are in close contact, so that their grooves form an opening through which the cable passes, approximately in line with the middle of the guide rollers. The drum is in the form of a deeply grooved wheel, the groove being U-shaped.

The cable guard or cover is a steel casting having a thickness of only  $\frac{2}{3}$  in.; the diameter is 4 ft. 6 in. and the

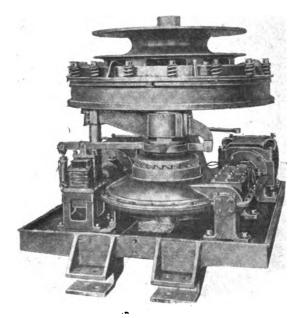

FIG. 9.—WINDLASS AND BASE ASSEMBLED COMPLETE, WITH MOTORS.

circular flange is 17 in. deep. This casting was pronounced to be beyond the possibilities of the ordinary open-hearth furnace by a number of steel foundries. The castings were eventually produced in the contractor's electric furnace, where it is possible to intensify the heat so as to make the metal flow more rapidly.

One of the most important parts of the locomotive is the "slip-friction" device, consisting of two special bronze rings mounted on the spider, as has been previously mentioned. Between these rings a steel disk is fastened to the rope drum; the amount of tension on the towline is adjusted by the pressure between these three disks, which is obtained by tightening spiral springs on the clamping ring (figs. 8 and 9). In order to make the slipping tension of the towline proportional to the pressure between the friction disks, a rubbing surface having a constant coefficient of friction was essential. In order to find such a metal, experiments were made, and it was found that a certain alloy possessed the required properties with a friction coefficient of 0.1. This metal also showed but very little difference in coefficient between starting and running. The results of the special tests were amply verified by the final test of the friction disks of each machine under the full rated towline pull of 25,000 lb. by means of a dynamometer testing outfit; all 40 machines were given this slip test 25 times from each cab, and all passed the Government requirement not to exceed a variation of 5 per cent. above or below the normal of 25,000 lb.

The winding motor is a 20-H.P. (one-hour rating), three-

phase, squirrel-cage induction motor, and has ample power to take care of any sudden pull on the towline up to 40,000 lb., which is well above the normal requirement. The speed of winding is at the average rate of 12 ft. per minute.

The rapid-coiling motor is permanently geared to the drum, and is of the same type, size and capacity as the winding motor. It is subjected to its maximum load when accelerating the heavy drum to the high speed required for coiling or paying out the rope, this being 16 times the slow winding speed at full load, or about 200 ft. per minute.

The slow-winding and the rapid-coiling motors are operated by similar controllers, and the circuits are electrically interlocked so as to prevent the application of power to either motor unless the controller of the other motor is in

the "off"

e "off" position.

Each of the two main traction motors has a rating of 75 H.P., and is of the slip-ring induction type, operated by a system of contactors with master controller in each cab. The motors, by means of the change in gearing from straight traction to rack-rail towing previously described, drive the locomotive at a speed of 2 miles per hour when towing and 5 miles per hour when returning idle. These motors act as induction generators running above synchronous speed when the locomotive is passing down the steep inclines, and thereby exert a retarding brake effect to keep the speed uniform.

The locomotives, which weigh 38½ tons each, have fully demonstrated in actual operation that the requirements contemplated by the engineers of the Isthmian Canal Commission have been successfully met.

We are indebted for the foregoing particulars and illustrations to the General Electric Co., U.S.A., through the British Thomson-Houston Co., Ltd., Rugby.

#### BATTERY-CHARGING FOR ELECTRIC VEHICLES.

BY FRANK BROADBENT.

THE increasing popularity of the electric vehicle again raises the important question of battery charging. method of charging a petrol car-viz., the pouring of a quantity of petrol into a tank—is simplicity itself, compared with the charging of an electric vehicle, which, besides being a relatively complicated process, takes about as many hours as the petrol car takes minutes. The introduction of the Edison battery, and the claim made for it, that it can be charged at a rapid rate without detriment, has reopened the question of constant potential charging for lead batteries. Although it has been recognised for many years that when fully exhausted a lead battery may with safety be charged at rates far in excess of what are called the normal rates, the common practice has been to charge at a practically constant current with a rising voltage until the battery gases freely. By this method a battery ordinarily requires charging for seven or eight hours to raise it from a fully exhausted to a fully charged state.

In ordinary practice with stationary batteries, it is not usual to exhaust a battery entirely. Thus on an isolated installation, such as that of a country house, the attendant charges two or three times a week, depending upon the He adjusts his voltage for the normal charging rate, and charges until the battery gases freely, the dynamo volts rising automatically as the current tends to decrease, due to the back E.M.F. of the cells. Gassing is not only detrimental, but wasteful, as the current consumed in converting the electrolyte into gas serves no useful storage purpose.

So long as a good modern battery on charge is not gassing or heating, it is usefully absorbing the current, so that if, when exhausted, the charging current is adjusted to a value just below the gassing point, it should take no Under these conditions, it will be found that the initial current may be as much as three to five times what is commonly reckoned as the normal current, the permissible excess depending upon the make of battery. Generally

speaking, if the applied voltage be approximately (but not exceeding) 2.3 volts per cell, the battery will take the current it can safely absorb, and as its back E.M.F. rises the current will automatically fall off.

For country-house work or other isolated battery installations, the constant-potential method of charging would necessitate a considerably larger generating plant than is ordinarily supplied. For instance, if we have a 54-cell battery whose normal charging rate is 50 amperes, the dynamo would be rated to give, say, 50 amperes at 100 to 140 volts or 7 kw., whereas if arranged for the constant-potential method, the output would need to be about 150 amperes, with a voltage not exceeding 125, or over 18 kw. Although the dynamo might be calculated on the basis of a 1-hour rating, and would therefore not be as large and expensive as the output suggests, the engine cannot be treated in the same way. The generating plant, therefore, unless used for other purposes than charging, would be much more costly. Where charging is done from public supply mains through a motorgenerator, both the motor and generator armatures might be rated on the 1-hour basis at the maximum current.

This question of plant capacity has, no doubt, perpetuated the approximately constant current method of charging for isolated installations, and as in many cases a quick rate of charge offers little or no advantage, this method is, all things considered, probably the most suitable. Moreover, we have to bear in mind that in fully charging a battery on the constantpotential method we do not save much time, because the rate of charge tapers down nearly to the vanishing point after a few hours. Its great advantages are that we can put back such a large proportion of the discharge during the first hour, and that if left on for the full time we can obtain a greater ampere-hour capacity than by the constantcurrent method; and that it is better for the battery. There appears to be no reason, however, why in ordinary installations we should not start with a current very much in excess of the normal, and then, if we have voltage enough, we can keep the current up to the normal when it falls to this level. In this way the charging time can be

materially shortened.

But the chief advantage of the high initial charge which the modern battery will stand is in connection with the electric vehicle. A brochure issued by the Chloride Electrical Storage Co., on "Boosting Charges for 'Exide' Vehicle Batteries," states the case very clearly. It is shown that when a battery is fully discharged a 30-minutes' boost at a pressure of 2.3 volts per cell gives us back 30 per cent. of the original capacity, and a 1-hour's charge puts back This means that if we have a battery vehicle 50 per cent. which will run for 40 miles on one complete charge, an hour's boost at the end of the run will carry us another 20 If, say, only 75 per cent. miles, that is, 60 miles in all. of the battery capacity has been used, corresponding to a run of 30 miles, an hour's boost will put back 42 per cent. of the original capacity, which, added to the unused 25 per cent., gives us a capacity equivalent to an additional 27 miles, or a total run of 57 miles. The advantages of this method, more particularly for commercial vehicles, which can return to headquarters at mid-day for an hour's boost, are very great. It means that a vehicle rated at 40 miles per complete charge can do 30 miles in the morning, and after an hour's mid-day boost is good for almost the A full charge would same distance in the afternoon. then be given during the night. Hence a 40-mile-a-day vehicle is converted into one having a range of almost 60 miles by taking a mid-day "pick-me-up."

Some useful experience has been recently gained in Hollywood garage in Chicago, equipped on the constant-poten-It is found that if a battery is only 75 per tial system. cent. discharged, it can be recharged up to 85 per cent. of its rated capacity in two hours, and up to 90 per cent. in three hours. It is not stated how long it takes to charge up to 100 per cent., but obviously the last 10 per cent. will take longer than two hours as the current is continu-As the average duration of charge is ally diminishing. given as  $3\frac{1}{2}$  hours, either the batteries are not discharged 75 per cent. on the average, or the charging rate is accelerated towards the end.

According to the description in the Electrical Review and Western Electrician, the method is not absolutely

a constant-potential method, as the initial current is limited to 60 amperes by means of a rheostat—apparently regardless of the size of the battery—the rheostat being gradually cut out during the first 10 minutes until the battery is directly across the line, after which the charge proceeds without further attention. It is not clear from the description what is the charging voltage per cell, but it may be assumed that after the first 10 minutes it is higher than would be desirable at first, and it is, no doubt, due to this that the charging period is found to be considerably less than on the old method.

This garage deals principally with passenger cars, of which many are run till midnight, so that they do not reach the garage till about 1 a.m.; and as they have to be delivered fully charged to the owners by 7.30 a.m., it is affirmed that the old method of charging would render this

almost impossible.

Energy is taken from the Commonwealth Edison Co. under a restricted-hour contract, no charging being permitted until 9 p.m.; the rate is approximately 1.7d. per unit delivered to the A.C. converters.

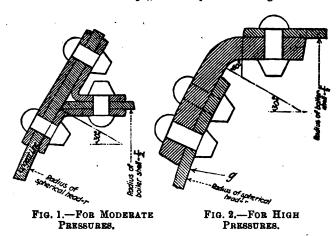

All cars are garaged at a flat rate of \$40 per month (say £8) for 40 to 42-cell cars, the cost covering charging, washing and polishing, adjustments, care of battery, and delivery to and from the garage. Smaller cars are garaged

for \$35 (say £7) per month.

The popularity of the commercial electric vehicle is growing so rapidly in England that there is a danger of its outstripping the growth of charging facilities. In a place like London, where electricity generating stations are so numerous, this might appear a somewhat remote possibility, but it is very doubtful if public generating stations are the best places for the purpose. Many of them are alternating-current stations, but, even so, they are not much worse adapted for charging purposes than those supplying direct current. In both cases, in order to do the business economically, motor-generators are necessary for obtaining the necessary charging voltage. True, it is possible to charge several batteries in series, but this is a very unsatisfactory method at the best, even if several batteries were available simultaneously; they would need careful watching to see that each received its proper charge, and that it was taken off at the right time and so on. It would, in fact, be such a nuisance that it would not pay any supply company to bother with the business on these The constant-potential method, on the other hand, is simplicity itself. The battery is simply plugged in and the voltage does the rest. Nothing can go wrong, assuming the battery itself to be all right. But even under the best conditions battery charging is hardly the sort of thing for which a central generating station is laid out. To do it properly, a charging garage should be erected and treated as a separate department. It should be put on the same basis as a bulk consumer and allowed to make its own terms with customers so as to show a profit on the business done. The department would, it is true, be in competition with outside garages, taking current from the same station. But it would be a fairer form of competition than if no separate department existed and batteries were charged in a haphazard sort of way (under the supervision of someone who had really no time to give to it) at rates sufficient only to cover generating costs. Under the charging-garage system it is quite possible that an outside garage would be able to compete in price with a generating station garage, because the rates paid to the station would depend upon the amount of business done, and this might very easily be in favour of the independently run garage, which would be erected in a convenient locality, and would be run by people who would lay themselves out to attract customers and to make the business pay.

#### STRESSES IN CONVEX DISHED ENDS.

SERIOUS accidents have occurred owing to the failure of the dished ends of steam drums, one some few years ago at a London electricity station having lamentable results. In Power the strength of these station having lamentable results. In *Power* the strength of these ends has been mathematically investigated by Mr. F. G. Gasche, of the Illinois Steel Co., who has noted the frequency with which failures have happened in the curve or bending of the flange, and to this special point attention is directed. Unfortunately, the author finds it necessary to say "for the sake of simplicity in the analysis it is necessary to assume a perfectly rigid cylindrical drum as a basis for establishing a numerical value for a certain reaction." These assumptions of things which do not exist always raise fears that the whole investigation is unreliable. However, the conclusion of three pages of very elaborate figures is that

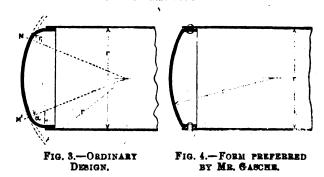

PROPOSED FLANGE CONNECTIONS FOR LARGE DRUMS WITH CONVEX HEADS.

large spherical heads should not depend on large-radius flange large spherical heads should not depend on large-radius flange fillets, but that the radius should be as small as possible even for moderate diameters of drum, and the two illustrations, figs. 1 and 2, show the connections suggested by the author to take the place of the simple flanged dish. Figs. 3 and 4 show the ordinary form of head, fig. 3 being the form condemned, and fig. 4 the form recommended with a very small radius between the curvature of the end and the flange. The dished end to a pressurvessel which has a radius greater than the radius of the cylindrical drum of which it forms the end is wrong in principle, for there must be a bending stress at the corner of the flange, and no amount of ingenuity of structural form can get over this. A head that is flatter than hemispherical will always be striving when under pressure to pull inwards the end of the this. A head that is flatter than hemispherical will always be striving when under pressure to pull inwards the end of the drum to a smaller diameter, thus making of the drum end a frustum of a cone, though very slightly, of course. Still, the stress will be enough to cause grooving round the most strained locus if exposed to water in the slightest degree corrowive, and wherever grooving is set up under water it may be taken for granted that there is excessive fibre stress. The dished ends of steam drums and the flat ends of Lancashire boilers, with their gussets and, formerly, bar stays are all concessions to appearance, and to the difficulties of forming hemispheres of plate. The Lancashire boiler head is now also a shallow dished end, and is exposed to the undesirable stresses noted above. Formulæ proposed for calculating dished ends are given in the article referred to. Comparisons between calculations for convex boiler heads based on various rules used in the U.S.A. are not very reassuring, for the

on various rules used in the U.S.A. are not very reassuring, for the allowable pressures found by three formulæ are in the ratio of 3, 2 and 1, the lowest value being that arrived at by the author, Mr. Gasche

In boiler work there can be no really reliable formula for any part exposed to secondary stresses. There may be a life of such parts that will endure until the boiler is sold second-hand, to fail in its new position from a sufficient number of millions of stress applications. But for high-pressure work all dishing carries in it the elements of its own self-destruction.

CONVEX DISHED ENDS.

As regards fig. 3, it always has appeared to the writer of this note that this form was based on an attempt to make a dished and look as though its stresses were all primary. But one cannot juggle with stress forms. Fig. 4, the new suggested form, may be better than fig. 3, but there is more risk in pressing out these small corners.

Mr. Gasche is forced by his investigation to the forms, figs. 1 and 2, which do but tell us that the dished end is inherently bad. As to fig. 2, more particularly we suggest grooving stresses

#### NEW ELECTRICAL DEVICES, FITTINGS AND PLANT.

#### G.E.C. Explosion-proof Switchgear.

The latest development in the range of G.E.C. explosion-proof switchgear for fiery mines is a 20-ampere, 500-velt, double-pole explosion-proof switch with fuses. It consists of a standard double-pole "Twinbreak" switch actuated by an external handle working through an explosion-proof gland. The interlock between the switch and the lid gives the device all the usual G.E.C. mistake-proof characteristics. The fuses, which are of the standard bobbin type, are contained in a separate fire-proof compartment; aroing shields and thorough fire protection are provided throughout. If desired the switch can be had without the fuses.

The j int between the lid and case is made by well-machined flanges giving a close metal-to-metal joint; special attention has been paid to the part where the switch spindle enters the case,

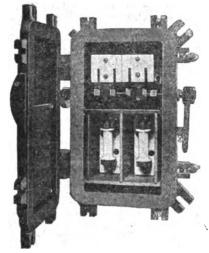

FIG. 1.-G.E.C. 20-AMPERE EXPLOSION-PROOF DOUBLE-POLE SWITCH WITH FUSES.

and a special flame-proof gland is provided. The switch is designed to take the standard G.E.C. flame-proof cable glands, which also afford a ready method of attaching the armouring of

which also alrord a ready method of streaming the almostring of the cable to complete the earth connection.

Further additions to the range of mining gear are explosion-proof fuses; these are contained in flame-proof cast-iron cases, which, as will be seen from the accompanying illustration, are of substantial design. As in the switches, particular attention

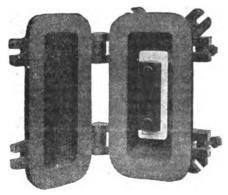

FIG. 2.—G.E.C. EXPLOSION-PROOF MINING FUSE.

has been paid to the flame-proof flanges, which effectively cool the products of any explosion inside the case. The fuse holders are of the G.E.C. Home Office bobbin type, and thoroughly protect the hand against dangers of shock, or from the effects of a blowing fuse. The cases are designed to take the standard G.E.C. flame-

The switches and fuses are made by the GENERAL ELECTRIC Co., LTD., of Witton, Birmingham.

MR. A. W. KANIS, of 66, Aldersgate Street, E.C., has brought to our notice the material called "Kasenoid," which has been developed to fill the place hitherto occupied by Galalith; it can also be used instead of ebonite and xylonite for many purposes. We have inspected a number of samples of this very interesting substance, which is of purely British origin and manufacture, and strongly recommend our readers who use this kind of material to look into it. The properties of "Kasenoid" are quite similar to those of Galalith; it is tough, resilient, easy to machine, non-inflammable, a good insulator, capable of being moulded to a certain extent, and is made in a variety of colours, either as sheet (up to 8 mm.) or rod (up to 12 mm. in diameter).

It can be turned and polished, and takes an excellent thread. Large quantities are being made for use in non-electrical industries also, and we understand that it is meeting with a very favourable reception.

#### The Dictograph.

THE GENERAL ACOUSTIC AND DICTOGRAPH Co., LTD., of 7. Sonthwark Street, S.E., have recently introduced a modified pattern of their loud-speaking telephones for single lines, as illustrated in figs. 3 and 4. Simplicity of operation is one of the chief features of the system; the caller simply lifts the receiver, fig. 3, and talks to the box in an ordinary tone, while the voice is received, or delivered, in a loud and clear tone at the telephone shown in fig. 4; the person at the latter station replies in the same way, but without using a receiver or mouthpiece—neither being provided. If

FIG. 8.—HEAD STATION.

FIG. 4.—STATION CALLED.

desired, the instrument shown in fig. 4 can be fitted with a pushbutton to call No. 1. The complete Turner-Dictograph system
provides for any number of stations connected with a master
station, such as that shown in fig. 5; this is fitted with a
loud-speaking receiver and a Turner transmitter, and the user
can sit at his deak or walk about the room while he talks
to his subordinates. The receiver shown is used when it
is desired that the replies shall not be heard by any
other person in the room; the set of lifting it from the hook

FIG. 5.-MASTER STATION.

cuts out the loud-speaking receiver. Each department is provided with a Turner station like that shown in fig. 6, which, it will be seen, has not a loud-speaking receiver. To call any station, the user presses the corresponding key. When the master station is called, a buzzer sounds and a shutter drops; the master station depresses the corresponding key, and is then connected direct with the caller, no one else being able to cut in on the line. The master station can also converse with any number of departments at once by throwing the various keys. by throwing the various keys.

Fig. 6.-Turner Telephone.

⁸ We have had an opportunity of testing the sensitiveness of the instruments, and can vouch for the ease and convenience with which one can both speak and hear at a distance of many feet from them, and without elevating the voice—indeed, a whisper can be heard plainly. The fatigue of holding a receiver to the ear is avoided, and for such purposes as dictating to a typist, for example, the system is admirably adapted.

## LEGAL.

BRITISH INSULATED & HELSBY CABLES, LTD., r. CRITTALL MANUFACTUBING Co.

MR. MUIR MACKENZIE, one of the High Court Official Referees, on March 22nd gave judgment in this action, in which the plaintiffs sought to recover from the defendants the price of an electric welding machine for making steel casement frames, and material in connection therewith.

in connection therewith.

The Referre, in giving judgment, said that the case was one which presented features of considerable difficulty, and it had been the practice of the Appellate Courts to require that the Judge who tried the case should give his reasons for the decision at which he arrived, and he had therefore thought it right to put his conclusions into writing. The action was commenced in February, 1914, and was originally brought to recover £104 2s. 2d., which was made up of two items as to one of which £47 16s. the ruary, 1914, and was originally brought to recover £104 2s. 2d., which was made up of two items, as to one of which, £47 16s., the defendants admitted liability and paid that amount into Court. As to the balance in dispute, the defendants said that the goods were supplied in connection with tests of an electric welding machine which did not prove satisfactory, and that they were, therefore, entitled to refuse payment. The plaintiffs said that the goods supplied were kept by the defendants and used by them for the machine which was delivered, and that they therefore could not refuse to pay. The plaintiffs claimed a further sum of £444, the price of the welding machine, together with a copper coil to the price of the welding machine, together with a copper coil to be used in testing. The defendants contended that the machine did not conform to the conditions to which by the contract it was to conform, and that they were therefore entitled to reject it. They counterclaimed for damages by reason of the failure. The first question to be decided was what was the contract between the parties. The defendants were makers of iron casement frames for windows, and before the negotiations with the plaintiffs they used gas for welding. They desired to adopt the more economical and more rapid process of welding by electricity. The two features of the plaintiffs' machine were, first, the generation of heat by electricity, and, secondly, the application of pressure to the ends of the bars where they were to be welded. Negotiations between the parties commenced in 1911, and continued during 1912, when the contract was made with the plaintiffs to supply a machine, and in the course of the negotiations specimens of the defendants' steel bars, which they wanted the machine to weld, were sent to the plaintiffs, so that they knew the work their machine would be required to do. The plaintiffs decided that they could make a machine as required, and an order was accordingly given to them. One speciality of the contract was that the machine should be capable of welding to an accuracy of  $_{1050}$  inch, that it should be able to produce 12 frames in an hour, and that it should be able to make frames of from 1 ft. to 10 ft. square. The order was given conditionally upon the work gas for welding. They desired to adopt the more economical and 10 ft. square. The order was given conditionally upon the work being submitted to the defendants for approval before the machine was put in hand. The work was to be of the best quality, and the electric conductors were to be of sufficient area to admit of continual working without undue heating. Part of the machine consisted of clamps made of copper which were to fit clorely to the consisted of clamps made of copper which were to fit clorely to the bars, and it was, therefore, necessary for the makers to have the proper dimensions of the bars. The defendants took steps for supplying the electricity for working the machine and for laying down the foundations for fixing it. The alternator was obtained and fixed by September 12th, 1912. Although the plaintiffs proceeded with the manufacture of the machine it was not ready within the time specified by the contract. In October the machine was ready, but the necessary clamps were not made, because the material had not been sent. The machine was sent by arrangement to the defendants works at Braintree, and they arranged to re-design the clamps and test it. The test was made in the presence of representatives of the plaintiffs; but the results were not satisfactory, and the opinion was that the cause of in the presence of representatives of the plaintiffs; but the results were not satisfactory, and the opinion was that the cause of failure was that with the clamps, as then made, their bars could not be properly welded. Subsequently the machine was tried again with unsatisfactory results, and the plaintiffs raised the point that the cause of the failure was the variation in the dimensions of the bars. The defendants, however, said that the welder was not fit for the work, and it was arranged that it should be sent back to plaintiffs to make alterations in order to overcome the difficulty occasioned by the variation in the dimensions of the bars. The plaintiffs declined to accept responsibility for the expense to which the defendants had been put, and difficulties arose in consequence, and when the plaintiffs began to press for the price of another electric welder, defendants objected to pay, on the ground that they had suffered a loss of between £400 and £500 by the failure to make the machine according to contract. Differences having make the machine according to contract. Differences having become acute, a meeting of the representatives of both sides was arranged for June 11th, 1913, when a certain settlement was arrived at. It was part of the terms of that settlement that the machine was to be made so that it could be demonstrated, by test with material to be supplied by the defendants, that it was commercially valuable. By September 1913, the plaintiffs having mercially valuable. By September, 1913, the plaintiffs having made alterations in the design of the clamps, they invited defendants to send representatives to see the machine at the plaintiffs' works; but it was found that the work was not good. Further tests were made afterwards, but it was not shown that the machine could weld the bars satisfactorily, and the defendants, therefore, refused to accept it. He found that the obligation of the plaintiffs under the settlement of June was to make the machine so that by test and demonstration it would reasonably satisfy the defendants

that it was fit for their requirements. The plaintiffs failed to do that, and he therefore found that the defendants were not bound that, and he therefore found that the defendants were not bound to accept the machine. As regards the claim for goods supplied (£56 16s.), they were delivered for trials of the machine; and as the machine failed, the defendants were not bound to keep the goods. That claim of the plaintiffs failed also. As to the counterclaim, the defendants alleged that plaintiffs failed to make and deliver the machine according to contract, and they claimed for the price of the alternator, the cost of the foundation for the alternator, the expenses connected with the work, the expenses of their representatives in attending the tests and some other of their representatives in attending the tests, and some other small incidental expenses. His opinion was that the plaintiffs were made sufficiently aware of the nature of the materials defenwere made sundently aware of the nature of the insterior dentals detendents used for their casement frames, and that the plaintiffs' contention that the contract was not broken because the material varied, was ill-founded. The defendants were entitled to reject the machine, because it was not in accordance with the contract. As to the machine not being up to the requirements, the plaintiffs said that it was put to work which it was not designed to do. Although the contention of the which it was not designed to do. Although the contention of the plaintiffs was erroneous, it was one which they were entitled to use. The arrangement which was come to disposed of the counterclaim for damages up to that date, and the claim of the defendants to recover such damages failed.

Their claim for expenses in relation to the tests was very much exaggerated. He directed that judgment in the action should be entered for the defendants, with costs of the action, and that judgment on the counterclaim should be entered for the plaintiff, with the costs of the counterclaim. As he had decided against both of the parties, he would stay proceedings under the judgment for ten days, and if both or either of the parties entered an appeal within that time the stay would continue until the appeal, which in the present state of the lists, would only be a short time.

Judgment was entered accordingly.

#### EXTRACTION OF WATER FROM PEAT BY ELECTRICITY.

FOR several days last week the Court of Appeal, composed of the Master of the Rolls and Lord Justice Phillimore and Mr. Justice Joyoe, was engaged in hearing an appeal by Witcarbonising, Ltd., from a judgment of Mr. Justice Warrington, in the Chancery Division, dismissing their petition for revocation of Letters Patent, No. 10,370 of 1911, granted to John Eustics Jameson, Oliver Harris Valpy and Edmund Arthur Buckle for improvements in the treatment of peat and the like. One of the claims was as follows:—"In the process of extraction of water from peat and

follows:—"In the process of extraction of water from peat and like substances, passing an electric current through the pulp of the same heated to a temperature of at least 100° C., under a pressure such that no steam is produced, substantially as described."

The petitioners (the appellants) applied for revocation of the patent upon the ground that it was invalid for want of utility and insufficiency of directions. It was proved that the water in peat was partly free and partly combined in the form of "hydrocellulose," and that the combined water could not be got rid of by pressure as the free water could. Prior to the patent it had been suggested that the water could be removed by the use of a comparatively high temperature and pressure. The patentees (the respondents upon the appeal) alleged that the result could be attained by the use of an electric current at a lower temperature. The petitioners contended that the only result obtained by the use of the current was due to its heating effect.

MR. JUSTICE WARRINGTON, in the Court below, held that the Mr. JUSTICE WARRINGTON, in the Court below, held that the specification described a process in which the electric current was used to effect the decomposition of the "hydrocellulose" without recourse for that purpose to heat, while the earlier process depended on the effect of heat alone; that the process was useful; and that the directions were not insufficient. His Lordship accordingly dismissed the petition with costs, and granted the respondents a certificate of validity. Hence the present appeal of the petitioners.

Mr. Welter K.C. Mr. Colefax, K.C. and Mr. Frost appeared in

Mr. Walter, K.C., Mr. Colefax, K.C., and Mr. Frost appeared in support of the appeal; and Mr. Bousfield, K.C., and Mr. J. Hunter Gray for the respondents.

The hearing was concluded on March 26th, when their Lordships

reserved judgment.

#### LIGHTING REGULATIONS.

AT the Hull Police Court on March 23rd, Mr. Frank Garnett Jones, manager for Messrs. Ostler, was summoned for failing to comply with the Order of the General Officer Commanding the Humber Defences, in regard to the reduction of shop lighting. It was stated by the police that the defendant had had lights in the about which were so at your that the will minimated the maken.

in the shop which were so strong that the defendant had highly street. There were 13 electric lights, and it was believed that half of these would have been all that were necessary under the present circumstances for the conduct of the business.

The DEFENDANT said he had forgotten about the regulation, but

INSPECTOR GALL stated that he had spoken to the defendant on

five previous occasions about the matter. The Bench imposed a fine of £10, including costs, and ordered the defendant to pay £2 2s. solicitor's fee, with an alternative of two months' imprisonment.

#### LONDON TRAMWAY ASSESSMENT APPEAL.

In the House of Lords, on March 26th, the Lord Chancellor and other Lords dealing with the matter gave their reasons for baving recently allowed the appeal of the L.C.C. in their tramways litigation with the Borough of Islington. We shall refer to the matter later.

#### MARCONI AGREEMENT DISPUTE.

AFTER a hearing extending over 15 days, Mr. Justice Avery and a special jury in the King's Bench Division, concluded the hearing of the action brought by Mr. John William Hamilton, civil engineer, and a former agent of the Marconi Co. in Australia, against the Marconi Wireless Telegraph Co., Ltd., claiming damages for alleged wrongful dismissal. He also claimed commission alleged to be due under an agreement under which he acted as the company's agent in Australia. The defendants pleaded that they were justified in their action and counterclaimed against the defendant in respect of alleged breach of duty.

justified in their action and counterclaimed against the defendant in respect of alleged breach of duty.

Sir Edward Carson, K.C., M.P., and Mr. Eustace Hills were counsel for the plaintiff, and defendants were represented by Mr. Duke, K.C., M.P., and Mr. Stuart Bevan.

SIE EDWARD CAESON, in opening the case, said that with regard to the commission certain sums were admitted, and on that part of the claim a question of construction arose which would be for his Lordship's decision. The jury would not be troubled with amounts as it had been agreed that that should be held over until the question of construction had been determined; the main claim for the jury would construction had been determined; the main claim for the jury would be for breach of agreement owing to the alleged wrongful dismissal under circumstances which, whether right or wrong, had brought about a loss of many years in the Colony in which the plaintiff was a man of influence and with long business connections. In was a man of influence and with long business connections. In 1910 it was agreed that the plaintiff should not as sales agent for the company in all the British Colonies situated within certain limits. The agreement was for three years, and would not terminate until May, 1913, but the company dismissed him in January, 1913. The plaintiff was to receive 5 per cent. of the gross value of sales in his territory, and if satisfactory the agreement was to continue for a further three years. In July, 1912, the plaintiff had an unfortunate dispute with Mr. Godfrey leaser. That was not put forward as a reason for determining the agreement, but from that time he was not allowed to do business for the company, and was time he was not allowed to do business for the company, and was refused all information as to what was going on. The reason given was that the Amalgamated Wireless Co. was to represent the

defendant company in Australia.

A great mass of correspondence was read, and several witnesses were called on both sides, Mr. Godfrey Isaacs being amongst those

who gave testimony for the company.

His Lordship concluded his adjourned summing-up on Wednesday, March 24th, and the jury, after an absence of four hours, returned to Court with a verdict for the plaintiff on all questions submitted to them.

Legal arguments on the questions of law raised in the case were

Legal arguments on the questions of law raised in the case were adjourned until the following day.

On March 25th, after hearing arguments by counsel on the finding of the jury, Mr. JUSTICE AVORY entered judgment for the plaintiff. Judgment, he said, must be entered for the plaintiff for £300 and £2,340 which had been awarded by the jury, and also on the counterclaim. There would also be judgment for the plaintiff for the sums admitted to be due—namely, £35 15s. 4d. and £82 2s. 9d. Further, he would direct an account as to commission on a 5 per cent. basis, and judgment for the plaintiff for the amount found due. In accertaining the commission, the prices must be taken to mean the contract price for the apparatus supplied for the installations carried out by the defendant company, plied for the installations carried out by the defendant company, where it was clear under the agreement he was himself to effect the contract for supplying the apparatus and installations.

Stay of execution was granted pending an appeal.

#### AN ABERDEEN CLAIM.

THE record has been closed in the Sheriff Court in an action at the instance of a local watchmaker against James Pirrie, electrical instance of a local watchmaker against James Pirrie, electrical engineer, 4, Hosefield Place, Aberdeen, for payment to the pursuer of damages laid at £700. The claim is in respect of bodily injuries caused to the pursuer through the alleged negligence of the defender, who, while driving a motor cycle and side-car along Cornhill Road, turned it on to the pavement and knocked down pursuer. Defender pleads that the accident was not due to any fault of his, but he has offered £140 in settlement of all claims against him by pursuer, which offer has been refused.

#### WAR ITEMS.

German Electrical Companies in War Time.—The Elektrotechnische Fabrik Rheydt (Max Schorch & Co.), of Rheydt, proposes to pay a dividend of 12 per cent. for 1914, as compared with 8 per cent. in the preceding year.

The gross profits of the Elektrochemische Werke, of Berlin and Bitterfeld, arising from the working community with the Griesheim-Elektron Chemical Works, and from manufacturing and investments, amounted to £86,000 in 1914, as compared with £84,000 in 1913. After defraying general compared with £84,000 in 1913. After defraying general expenses and providing for depreciation, the accounts show net profits of £62,000 as against £61,000 in the previous year, permitting of the payment of a dividend of 10 per cent, as in 1913. Under the company's agreement with the Griesheim-Elektron Works, which was concluded in 1889 for a period of 30 years, the former leased most of the works plant to the latter for the manufacture of chloride products and alkalies, carbide, sodium and magnesium.

The directors of the A.G. Mix und Genest, of Berlin, Telephone and Telegraph Works, state that the development of the works in 1914 was such that it was only possible to meet the requirements by a rapid accommodation of working methods to the new problems raised by the war. In addition meet the requirements by a rapid accommodation of working methods to the new problems raised by the war. In addition to the usual business a considerable turnover was also effected by the execution of war orders, although the profits realised by the inland branches were less than in the preceding year in consequence of the war. On the other hand, the oversea business had been almost at a complete standstill since the outbreak of hostilities. It was proposed to liquidate the subsidiary company in Italy, but this would not result in any loss as compared with the balance sheet. The gross profits amounted to £107,000. After meeting general expenses and setting aside £18,000 for depreciation, the net profits are £60,000, as against £14,000, and a dividend of 12 per cent. is in contemplation, as contrasted with 4 per cent. in 1913.

The report of the Kabelwerk Duisburg, of Duisburg, characterises the past year as having yielded gratifying results, which are attributed, in addition to the great activity in the first half of 1914, to the favourable purchase of raw materials. After appropriating £23,000 for depreciation, as against £35,000 in 1913, the net profits are returned at £56,000, as compared with £46,000. The reduction in the amount set aside for depreciation is explained by the fact that a sum of £20,000 for special depreciation was allocated in 1913, thus bringing the book value of the machinery account down to one shilling. It is proposed to pay a dividend of 18 per cent. for 1914, as contrasted with 16 per cent. in the preceding year, and to place £12,500 to the guarantee fund for foreign debt risks and £12,500 to the contingency

in the preceding year, and to place £12,500 to the guarantee fund for foreign debt risks and £12,500 to the contingency fund, leaving £1,800 to be carried forward. The report states that the extensions of the works were interrupted by the outbreak of war, but it is hoped to complete them by the

end of June.

Power Transmission and the War.—How the activity of a company can be adversely affected by the prevalence of war when a portion of its area of supply is situated within one part of the war zone is strikingly illustrated by the experience of the well-known Rheinfelden Power Transmission Co., of Rheinfelden, down to the end of last year. During the first seven months of the year, the company's report states, a further development in the utilisation of the hydro-electric works at Rheinfelden and Wyhlen took place the increase in consumption having almost entirely the hydro-electric works at Rheinfelden and Wyhlen took place, the increase in consumption having almost entirely absorbed the output of the works. On the outbreak of war, however, the first effect on the works was the withdrawal of the German workmen; and secondly, the large bulk consumer represented by the Upper Rhenish Power Works Co., of Mulhausen, was compelled almost entirely to suspend the supply from August 8th, after the transmission lines and various installations in Alsace had been severely damaged by incidents of the war. In addition, the Wiesenthal railway, which receives electrical energy from the Wyhlen Works, was also compelled to stop the electrical service of trains. The result of these unfavourable developments was that the total delivery of energy, which amounted to a load of approxiwas also compened to stop the electrical service of trains. The result of these unfavourable developments was that the total delivery of energy, which amounted to a load of approximately 23,000 kw. at the end of January, 1914, receded to 4,000 kw. by the middle of August, which was almost uniformly divided between the Rheinfelden and Wyhlen works. It was, however, possible, in connection with the Upper Rhenish Power Co., to repair the transmission lines in Alsace in the first week of September, and the normal delivery of energy to Mulhausen was then resumed. The installations of most other consumers were also brought into operation gradually, so that the total load was increased to about 17,000 kw. in the last three months of 1914, but a reduced consumption prevailed down to the end of the year in the case of the Wiesenthal railway, an electro-chemical works, and the Zell Electricity Supply Co.

Lampmakers and the War.—We learn that the employes of the Osram and Robertson Lamp Works have collected by weekly subscriptions, up to March 24th, a total of £349 towards the Prince of Wales's War Relief Fund. The Lamp Works have 73 men who have joined H.M. Forces, and information has been received of four of the men being wounded. Fortunately, so far, no fatal case has been reported.

reported.

New Zealand.—An Auckland firm is prepared to take up agencies for United Kingdom manufacturers of cast-iron agencies for United Kingdom manufacturers of cast-iron pipes and fittings, steel girders and channels, wrought-iron and overhead cables and electric wires, motor-car accessories and tires. A firm of electrical engineers and contractors in Invercargill desires to represent United Kingdom manufacturers of all classes of electrical machinery, appliances and fittings. The names may be ascertained at the Board of Trade Commercial Intelligence Branch, London, but communications should be sent to H.M. Trade Commissioner for New Zealand, P.O. Box 369, Wellington.

Australia.—Representation for a British firm of electric crane-makers is wanted by an agent in Melbourne, whose name may be ascertained at the Board of Trade Commercial Intelligence Branch in London. Communications to H.M. Trade Commissioner for Australia, Commerce House, Mel-

Frade Commissioner for Australia, Commerce House, Mel-

war Bonus Protest.—The Executive Committee of the Manchester Ratepavers' Association has organised a strong protest against any proposals to grant municipal employés a war bonus.

Russia.—It is announced that a meeting of prominent British and Russian merchants was held in London (at 1, Charing Cross Road, S.W.) last week, at which it was resolved to form the "Russian Chamber of Commerce in London" for the purpose of facilitating the promotion and extension of trade between the two countries.

Italy.—The British Chamber of Commerce is forming a branch at Pome

branch at Rome.

Board of Trade Assistance.—The Board of Trade Commercial Intelligence Branch has issued list No. 13 (for the week ending March 20th) giving particulars of further inquiries received for sources of supply of goods.

Roll of Honour.—The "City Press" states that Private W. W. Pullen, Engineers' Section of the Royal Naval Division, who died on March 12th at the R.N. Hospital, Malta, was assistant engineer at the Leatherhead Power Station. He was a student under Prof. S. P. Thompson, at Finsbury. In the early months of the war he responded to the circular issued by the President of the Institution of Electrical Engineers.

Private Jas. Henry Gardner, of the King's Own Rifles, formerly a motorman in the employ of the Blackburn Corporation Tramways Department, died last week at Manchester, after the amputation of a foot. He was 30 years of age, and was wounded in France. He was buried with military honours, and the funeral was attended by about military honours, and the funeral was attended by about forty tramwaymen.

Personal.—"London Gazette" announcement:—Territorial Force: Electric Lights Company, Renfrewshire (Fortress) Engineers; Cadet William MacNicol Adam, from Inns of Court Officers Training Corps, to be Second Lieutenant. March 27th.

The Ilford Urban Council has declined to grant leave of absence to Mr. A. Glazier, engineer-in-charge for the Electricity Works, who has been offered a post as electrician in the Mechanical Transport Service Corps for the duration of the war, as the staff is already short-handed, 20 having joined the forces.

joined the forces.

Mr. Thos. Cooke, electrician, Cambridge, and Mr. John Herbert Merry, electrician, Cherryton, have joined Kitchener's second army, being recruited at Cambridge.

#### CORRESPONDENCE.

Letters received by us after 5 P.M. ON TUESDAY cannot appear until the following week. Correspondents should forward their communications at the earliest possible moment. No letter can be published unless we have the writer's name and address in our possession.

#### Power and Lighting Rates.

I think it will certainly interest many of your readers to have the following information on the subject of electricity

charges for photo-printing purposes, and I agree to your making what use you desire of such information.

The Ilkeston Town Council at its last meeting, held on March 2nd, passed the following resolution:—

"Resolved that the Town Clerk be, and he is hereby, instructed to prepare a case for the opinion of counsel as to the council the Corporation to surply about the photography. power of the Corporation to supply electricity to photographers for photo-printing purposes at power rates; and that such case be submitted to Mr. W. E. Tyldesley Jones, the editor of 'Will on Electric Lighting, Power and Traction,' for his opinion'." opinion.

Mr. W. E. Tyldesley Jones's opinion is not yet to hand, but the circumstances relating to the position at Ilkeston have also

been laid before the Local Government Board.

I might explain that I was Chairman of the Ilkeston Corporation Electricity Committee, and the following five questions of mine were put to the Board:—

1. "Is it illegal to supply current for photo-printing at power rates?"

2. "If we supply at power rates are we liable to be surcharged?"

3. "Can you quote any test cases bearing on the point?"

3. "Can you quote any test cases bearing on the point?"
4. "Can you give me the names of a few towns where they have L.G.B. auditors?"
5. "Can you tell me where I can get a complete list of the towns who have L.G.B. auditors?"
The last paragraph of the letter to the Board was a request that instructions be given to the auditors that no surcharge ha made in cases where rower rates were being charged for be made in cases where power rates were being charged for photo-printing purposes.

The following is a copy of the Local Government Board's

reply:-

[Copy.] LOCAL GOVERNMENT BOARD, WHITEHALL, S.W.

Sir,

Photo Printing and Auditors, etc.

I am directed by the Local Government Board to advert to your letter respecting the cost of electrical energy supplied for the purpose of photographic printing.

In reply to the questions numbered 4 and 5 in your letter,

I am directed to forward to you the accompanying list of councils of municipal boroughs whose accounts are audited by district auditors, and to state that the accounts of all urban district and rural district councils also are subject to such

In reply to the questions numbered 1 and 2, I am to state that these matters seem to depend upon the terms of the special Act or Provisional Order under which the supply is given. The Board are not aware of any provision in the general law upon the subject.

In further reply to these questions and to question 3, I am to state that the Board are not aware of any decision of the Courts upon the point, and that they do not find that it has arisen on an appeal made to them from a decision of a district auditor. Apart from such an appeal they would have no power to decide the point.

The Board are not empowered to give any such instructions as are suggested in the last paragraph of your letter.

I am, Sir, Your obedient servant, (Signed) D. Dolton, Assistant Secretary.

I think the above sentence which reads "The Board are not aware of any provision in the general law upon the subject" is very significant.

(Coun.) William Smith.

Ilkeston, March 27th, 1915.

## BUSINESS NOTES.

Bankruptcy Proceedings.—George Driver & Son, electrical and mechanical engineers, Hythe Road, Willesden Junction.—The first meeting of oreditors was held on March 23rd Junction.—The first meeting of creditors was held on March 23rd at the London Bankruptcy Court. Mr. E. Leadam Hough, Senior Official Receiver, reported that the business was commenced in 1891 by Mr. G. H. Driver at Euston Buildings, Euston Road, and two years later that gentleman was joined in partnership by Mr. E. W. Fladgate. In 1895 the present debtor, James Proctor Kyd Clark, became a partner, and put in \$500 for a third share of the business, which was removed to Hythe Road in 1899. Mr. Eladgate retired during the energing received the process that he was Fladgate retired during the ensuing year, under terms that he was to receive 5 per cent. per annum on his capital of £1,500 which he left in the business. It was further arranged that he was to receive that interest during his life, with succession to his sister. The business was continued by the debtor and Mr. Driver under the old style as equal partners until 1903, when the latter died, and the debtor arranged to pay out his late partner's capital of £1,600 to his executors by instalments. He subsequently continued the business alone, and at that time arranged to pay Mr. Fladgate £750 of his capital by instalments, and of that he had paid £250. The business was solvent at that time, and was continued by the debtor. business was solvent at that time, and was continued by the debtor till last September, when he agreed to sell the goodwill and all the properties connected with the business for £200 to a Mr. W. J. Thomas, who also agreed to take over the trade debts and the liability to Mr. Fladgate. He obtained the £200 in October, and had used the money for living expenses. In 1901 the debtor and Mr. Driver formed the Driver Automatic Weighers, Ltd., to take over from the firm the goodwill of a patent weighing machine business. The capital of the company was £10,000, in 5,000 preference and 5,000 ordinary shares of £1 each. In 1905, in consequence of competition, it was decided to realise the bulk of the assets of the company, and from the proceeds of sale the claims of the creditors and preference shareholders were discharged. No statement of affairs had been lodged, but the debtor roughly estimated his liabilities at £1,850, of which £1,700 was due to the petitioning creditor in respect of a disputed claim, and he had no assets of any kind. It was a question, added the chairman, no assets of any kind. It was a question, added the chairman, whether the debtor intended by the sale of his business to Mr. Thomas to defeat the claim of the petitioning creditor. In the absence of any offer the case was left in the hands of the Official Receiver, to be wound up in the ordinary course of bankruptcy.

Private Arrangements. - THE BRITISH PROME-THEUS CO., LTD., Salop Street, Highgate, Birmingham, Warwick.

—In pursuance of Sec. 188 of the Companies' (Consolidation) Act, 1908, a meeting of the creditors interested herein was held on March 25th at the offices of Mesers. Poppleton & Appleby, chartered accountants, 26, Corporation Street, Birmingham, when an approximate statement of affairs was presented showing the position as at January 23rd last, According to this the liabilities totalled £1,590, of which £1,490 was due to the trade, the balance being in respect of a liability under lease as to repairs. The assets were £1,590, of which £1,490 was due to the trade, the balance being in respect of a liability under lease as to repairs. The assets were estimated to produce £9,164, and comprised etock in trade £3,832; patent rights, £300: book debts, £1,700; plant and machinery, £1,286: tools and patterns, £211; office furniture, £250; and cash in bank, £1,585. After allowing £6,943 for the claims of the preferential creditors and debentures, the net assets were reduced to £2,221, the estate showing an apparent surplus of £631. It was stated that the company had been adversely affected by the war. The accumulated losses between 1902 and 1914 had amounted to £5,700, while £9,200 had been written off the assets. The loss from July 14th last to date was £1,800. The matter was left in the hands of Mr. C. T. Appleby, as liquidator, with a committee consisting of Messrs. E. Pugh & Co., Mr. Robert Rigby and Mr. Cripwell representing oreditors. oreditors.

Sydney Contracts.—The Sydney Municipal Council has opted the following motion, viz., "That in view of slight adopted the following motion, viz., informalities in tenders having cau informalities in tenders having caused lowest tenders to be rejected, entailing loss to the citizens, it is desirable that a clause in conditions of tendering be inserted to admit of such informalities being waived and the tender being considered, provided the Council is satisfied that such informality is bond fide and not prejudicial to the true interest and meaning of the specification and conditions as to tendering."—Tenders.

-G. Braulik, 8, Lambeth Hill, E.C.-Composition.-Mr. G. E. Corfield, the trustee, reports that the business under his supervision has been continued upon a satisfactory basis. He has now declared the fourth and final instalment of 2s. 6d. in the £, making 10s. in all. In regard to new goods which have been or may be ordered in future, Mr. Braulik will take all responsibility.

Trade Announcements.-MR. T. J. READ, electrical engineer, of 94. Victoria Road, Swindon, announces that owing to his departure from the town he is giving up the business.

MR. FRED EDMONDS, electrical engineer, has commenced business at Highworth, Swindon.

Owing to heavy demands which have been made upon them for cables and flexible cords since Garman supplies were cut off, MESSES. CAVE & HIGGIN, LTD., have removed to larger premises at 19, Hardman Street, Manchester. They will forward particulars on application.

## LIGHTING and POWER NOTES.

Aberdeen.—During February 1,118,630 units were generated at the municipal power station, an increase over the corresponding month last year of 104,750 units.

Australia.—The Launceston (Tas.) City Council has decided to ask the Government to submit terms and conditions for a supply of energy from the Great Lake plant. It is estimated that, at a cost of £60,000 for transmission, 10,000 HP. could be brought to Launceston. Unless satisfactory terms can be obtained, an auxiliary steam plant will have to be installed.

The Maldon (Vic.) Shire Council has, owing to the prospect of an increased price for gas, decided to obtain particulars from other municipalities as to the cost of electric lighting.

The Dalby (O.) Council has been granted an order authorising

The Dalby (Q.) Council has been granted an order authorising the installation of the electric light within the municipality.

The Table Bay (Tas) Municipal Council is considering the question of borrowing £6,000 for the Wynyard electric lighting

The North Illawarra (N.S.W.) Council has decided to light the municipality by electricity, the work to be carried out when funds are available. It was also resolved that the various townships should be lighted on a ratepaying basis.—Tenders.

Aylesbury. - Public Lighting, &c. - The U.D.C. has decided to apply for a loan of £400 for street lighting by electricity. It is proposed to provide 62 new lamps and convert 31 existing gas lamps. A contract has been made with Mesers. Hazall, Wateon & Viney, who have guaranteed to take not less than £200 worth of energy per annum. A loan of £250 is also to be applied for to cover the cost of wiring the Town Hall and adjoining premises: current for power will be available by the end of April.

Ballymena.—The B. of G. was recently informed by the L.G.B. that the provision made by Parliament for local loans was fully allocated, but if the Guardians were unable to obtain the £3,500 required for heating and electrically lighting the Workhouse and new hospital, they might renew their application to the L.G.B. in a month's time.

Barking.—PROPOSED LOAN.—The U.D.C. has applied to the L.G.B. for a loan of £18,000 for extensions and additional plant at the electricity works.

Barnet.—Workhouse Lighting.—The B. of G. has decided to defer the acceptance of a tender for the electrical installation at the Workhouse for the present, those received being so much above the estimate. The North Metropolitan Electrical Supply Co. is to be asked to quote terms for a supply of current for lighting and power for seven or ten years.

Blackpool.—The output of the electricity works for February showed an increase of 27,985 units on February last year; this advance has been made despite the falling-off in the supply of 16,908 units for public arc lamps, and 8,700 units to the tramways. For the 11 months the total increase has been 353,356 units, although the public arc lamps show a decreased supply of 40,041 units.

Bolton.—Public Lighting.—The B. of T. has auctioned the erection of overhead wires for the lighting of Long Lane, Breightmet, by electricity.

Boston.—L.G.B. INQUIRY.—At an inquiry held on March 24th into the application of the T.C. for a loan of £3,600 for a refuse destructor, the inspector (Mr. B. H. Bicknell), intimated that the Council would not be able to get the money, because the Local Loans Commissioners would not grant it, and it would be very difficult to get it elsewhere until the Treasury had withdrawn its circular.

Broadstairs.—Public Lighting.—The U.D.C. has asked the Thanet Tramway and E.L. Co. to install a sample electric lamp in connection with its offer for public lighting where the

Easebourne.—Public Lighting.—The P.C. has received an offer from the Midhurst and District E.L. Co. to light the streets by electricity.

Eccles.—The terms on which the Manchester Ship Canal Co. is prepared to allow the Corporation to take water from the Bridgewater Canal for condensing purposes have been before the Public Lighting and Electricity Supply Committee, and the latter has decided to intimate that it cannot agree to the terms.

- COAL v. OIL FUEL. — Messrs. Blackmore Finchley. and Co., the District Council's contractors for the supply of coal

to the electricity department, have intimated that they are unable to comply with the terms of their contract.

The electrical engineer reports that the deliveries of oil fuel were being satisfactorily maintained, and that this, together with the oil engine, was of the greatest assistance in the present situation.

Haslingden.—Loan Proposals.—The L.G.B. has notified the Corporation, in reply to an application for sanction to notined the Corporation, in reply to an application for sanction to a loan of £12,000 for electricity extensions, that only work absolutely necessary should be proceeded with, and that capital expenditure should be limited as much as possible. The Electricity Committee has agreed to act in accordance with the communication.

Heston and Isleworth.—The Electricity Committee has decided to charge for current supplied to rifle ranges on the same basis as that fixed for power supply,

Hull.—PLANT EXTENSIONS.—In connection with the proposed extensions of the electricity works, we understand from Mr. Magoris, deputy city electrical engineer, that the E.L. Committee was recommended to install the 5,000-kw. turbine set, one boiler and feed pump, and to defer for the present, a second boiler, cooling plant, coal-handling gear, &c. This modifies the information contained in our note published last week, which was derived from local sources. derived from local sources.

Ilford.—The Electricity Committee has given instructions for all agreements in respect of wiring, fittings and apparatus on hire, agreements for maintenance, &c., to be terminated. In view of the great increase in the cost of coal, the electrical engineer recommends fitting two dry-back boilers with mechanical stokere

India.--CAUVERY FALLS.—The chairman of the Nundy-In III.—CAUVERY FALLS.—The Chairman of the Nundy-droog Co., Ltd., speaking at the annual meeting in London last week, referred to the slight increase in costs, which was attributable to a protracted drought cocasioning a shortage of water in the Cauvery River during March, April, May and June, necessitating the use of steam power in place of electricity. Years ago, when they first discussed the question of introducing electric power, they told shareholders that the steam plant would be kept in repair, properly cleaned so as to be used in any emergency. They there properly cleaned, so as to be used in any emergency. They, therefore, fell back upon it for several months. The Mysore Government was now constructing a large storage reservoir, which in due time would ensure a constant supply of power under the Cauvery scheme. It might not be entirely completed this year, but it would afford some additional protection, and under ordinary circumstances they need not look forward to a stoppage again on account of shortage of water.

A licence has been granted to Messrs. Crompton & Co. to supply electricity to the town of Agra.

Ipswich. — THREE-PHASE EXTENSIONS. — Extensions have rec-ntly been completed and put into operation whereby the whole of the eastern district of the town, which is largely residential, has been provided with an electric supply from four-wire, three-phase low-tension mains, the pressure being 400 volts between phases and 230 volts from any phase to neutral; 5'2 miles of main have already been laid. The district is supplied from two brickbuilt static transformer sub-stations, which are fed from duplicate three-phase feeders at 3,000 volts. On their way to the eastern district the duplicate feeders, which are each 2.75 miles long are looped into a rotary converter sub-station in the foundry district,

designed to supplement the existing continuous current supply to the consumers in that neighbourhood. The three-phase supply at the power station is at present provided by a rotary converter, running inverted on the D.C. supply, and having a normal alternating-current output of 312 K.V.A. As a stand-by for this there is ing-current output of 312 K.V.A. a 300-K.V.A. three-phase alternator connected to one of the original Reavell tandem compound three - crank engines running at 375 R.P.M. Automatic voltage regulation is provided for on both the rotary and alternator by means of a Taylor-Scotson regulator, this being the third of that make of regulator installed at Ipswich. The two rotary converters in the foundry district sub-stations are arranged for a normal output of 250 kW. The whole of the generating and converting plant has been supplied by the British Westinghouse Co., and the main switchboards have been supplied by the Switchgear Construction Co. The transformers in the static sub-stations have been supplied by Messrs. Ferranti.

Keighley.—The R.D.C. has given permission to the Corporation to lay a cable to the Keighley Joint Hospital, on the understanding that no supply is given to the East Morton

Kingston.--INCREASED PRICES.—In accordance with the recent resolution of the Council, raising the prices of electricity for lighting, the E.L. Committee has increased the flat rate to 5½d. per unit, the m.d. rate to 7½d. and 3½d. per unit, the tariff to churches to 5d. per unit, and for public lighting by 10 per cent.

Leeds.—Permission has been granted by the Morley Corporation to the Leeds City Tramways Committee to lay cables giving a temporary supply of electricity to Messrs. A. Marshall and Sona, of Perseverance Mills, the newer portion of which are electrically equipped.

Leyton.—Proposed Loans.—The Electricity Committee of the U.D.C. recommends an application to the L.G.B. for sanction to loans of £17,158 for additional plant at the power station and £1,000 for services.

Llandudno.-NEW PLANT.-The U.D.C. has decided, in view of the L.G.B.'s refusal to sanction a loan of £2,000 for extending the generating plant at the electricity works, to pay for the plant out of the reserve fund.

-The directors of the London Electricity Supply Companies have decided to raise the price of energy as m April 1st.

A new lighting order has been issued by the Commissioner of Police for the City, which amends the hours during which the inside lighting of shop fronts must be reduced, to from 7 p.m. till sunrise during the month of March, from 7.30 p.m. till sunrise during the month of April, from 8.30 p.m. till sunrise during the month of May, from 9 p.m. till sunrise during the month of June, and until further orders. This order, which came into force on March 22nd, does not affect the time fixed for the carrying of a red rear light by vehicles.

POPLAB.—The Electricity Committee has had under consideration the question of the disposal of the surplus profits of the electricity undertaking, and also a profit-sharing scheme, and recommends that from April 1st the charge for private lighting shall be reduced from 5d. and 4d. to a flat rate of 3d. per unit, and for long-hour consumers from 2½d. to 2d. per unit net; domestic consumers charge from 12½ per cent. on installation expenditure to 8½ per cent, and from £4 per RW. to £3 per KW. standing charge for general lighting purposes; also that a limited number of fans and radiators of standard type shall be loaned to consumers free of charge, in order to develop this be loaned to consumers free of charge, in order to develop this class of supply. The Committee also reports that a reduction in the price of power can be effected in the near future if the policy of writing down capital in respect of obsolete plant is continued, so as to reduce the outstanding capital per RW. installed below £25. The Committee recommends, as a definite system of disposal of future profits, that after providing for all usual maintenance charges, and writing down service and instrument loans, the floating balance of the undertaking as set out in the balance-sheet of the palance of the undertaking as set out in the balance-sheet of the annual report shall be at least equal to 10 per cent. of the total income in any year. Of the remaining balance, 40 per cent. shall be devoted to the relief of the rates, 40 per cent. be placed to the credit of machinery capital account to provide for obsolescence of plant, and 20 per cent. be dividend amongst the workmen and staff of the undertaking up to £1,200 and on further amounts the bonus be reduced one-half. It is proposed to appropriate an amount equal to a 1d. rate from the electricity fund for the relief of rates. the relief of rates.

L.C.O.—The Treasury has drawn attention to the action of the Hackney B.C. in obtaining a loan of £10,000 from its bankers, which the Treasury had declined to allow it to borrow from the L.C.C.; although Treasury approval is not necessary in all circumstances before sums are borrowed by B.C.'s from their bankers, it should be understood that if a Council insists upon incurring capital expenditure against the wishes of the Treasury, which is acting with a view to the general interests of the nation in existing circumstances, sanction will not be given by the Treasury or

ing circumstances, sanction will not be given by the Treasury or the L.G.B. in the case of any further application for approval of borrowing for any purpose whatever.

The L.C.C. Finance Committee recommends the Council to sanction the borrowing of £4,000 by the Stoke Newington B.C. for mains and meters, providing the Council undertakes not to incur further capital expenditure which is not really necessary.

STEPNEY.—The B. of T. has approved the supplementary agreement with the Shoreditch B.C. for a limited bulk supply.

Mountain Ash.—Proposed Loan.—The U.D.C. has decided to meet the cost (about £550) for the provision of a substation in connection with the electric supply at Abercycan, out of the rates, and to apply to the L.G.B. for a loan of £2,650 for carrying out the other portion of the scheme.

Penzance.—The Penzance and District Electric Supply Co. announces that it is extending the mains in the town, particularly in the Lescud Jack district, and is wiring premises on the instalment system.

PLANT.—The Electricity Committee Perth.--New recommends the purchase of certain generating plant at Lough-borough, for £1,835; a deputation recently inspected the plant with a view to purchasing it, and thus avoiding further borrowing.

Portaferry.—E.L. Scheme.—The L.G.B. has granted the application of the Downpatrick R.D.C. for powers to carry out a lighting scheme for Portaferry. The area embraces the three townlands of Ballymurphy, Ballyphilip and Tullyboard.

Shipley.—Owing to the high price of copper, and the high rate of interest on loans, the Electricity Committee has deferred the carrying out of certain extensions for the present.

Upper Beeding.—Proposed E.L.—At a meeting of the P.C. on March 23rd, a letter was received from Mr. C. B. Oxley, of Steyning, offering to supply electricity for public lighting at 1s. per week per lamp, and also for private consumption. The Council decided to discuss the matter with Mr. Oxley at the next meeting.

#### TRAMWAY and RAILWAY NOTES.

Blackpool.—The total tramway receipts from April 1st last year to March 18th this year amounted to £74,393, a decrease

Chester.—YEAR'S WORKING.—It is estimated that the gross profits from the tramways for the year just closing will be £5,087, as against £5,045 last year.

Colwyn Bay.—TRAMWAY EXTENSION.—The electric tramway line from Colwyn Bay to Old Colwyn has now been completed and fully equipped. The extension is nearly 2 miles in length, and will serve a considerable population on the route as well as the residential and industrial population at Old Colwyn and Llysfaen.

Continental.-ITALY.-The Communal Authorities of Rome have been authorised to construct and work, by electric traction, an extension of the Piszza Colonna—Piszza San's Croce tramway, and also an extension of the line from the Via Po to the Zoological Gardens. The "Società Elettrica Sarda" has also been authorised to construct and work an electric tramway system in the town of Cagliari.

Edinburgh.—TRAMWAY INQUIRY.—An inquiry has been held under the Private Legislation Procedure (Scotland) Act, into the prov. order promoted by the Corporation. A proposed tramway branch to Colinton Village and Redford Barracks was opposed by the Colinton Tramways Co. and the County Council. Mr. Cooper, K.C., explained the Corporation proposal to use self-propelled cars, and Mr. A. H., Campbell, the burgh engineer, gave evidence in support of the scheme. Mr. Stephen Sellon said he did not think the Corporation scheme would affect the company's not think the Corporation scheme would affect the company's scheme very much, but it would be better for the shareholders if the latter scheme disappeared. Mr. J. B. Hamilton and Mr. Sherherd (Edinburgh Tramways Co.) also gave evidence, while the County Council opposed on account of the narrow roads, and for the company it was pointed out that they hoped to commence construction before February 1916.

struction before February, 1916.

Mr. Macmillan, K.C., for the Colinton Tramways Co., said the company had been authorised by Parliament to construct the line in the full knowledge that it was to be used as a track for the conveyance of material till the population came.

Mr. Cooper, K.C., for the Corporation, said that the T.C. might have been led to consider the purchase of the Colinton Tramways Co.'s undertaking, but it was resolved that under no circumstances would it take over the Colinton tramways along with the company's obligations to the War Office at this time.

The Court eventually decided that the Corporation be granted power to construct a line in the Corstorphine district and in the Colinton area, by Firhill, by circular route to the Braid Hills.

In regard to the portion of the route from Craiglockhart to Colinton, an offer was made by the Colinton Tramways Co. that the Corporation should purchase the rights there at £9,000, but this offer was refused by the Corportion, and that part of the foute was withdrawn.

Glasgow.—Female Conductors.—As an experiment, and in view of the shortage of men, women conductors are being tried on the Corporation tramways.

Hull.—The T.C. is applying for powers to construct two additional lines of tramway in the city.

Ilford.—The U.D.C., last week, had a long discussion on a motion to the effect that, in view of the financial condition of the tramway undertaking, the best available expert advice be called in to assist the Council in formulating a scheme by which the undertaking can be placed upon a sound commercial basis. Owing to the lateness of the hour, the discussion was adjourned until the next meeting. until the next meeting.

-In our issue of March 19th we stated Lancashire.that owing to recruiting, the number of men carried on the South Lancashire Tramway Co.'s system in the early morning and after-noon was showing a material shrinkage. We understand from Mr. E. H. Edwardes, the manager, that this is incorrect. As a matter of fact, the workmen's receipts happen to be above the average.

London.—The Finance Committee of the L.C.C. has received an intimation from the Treasury that consent will not be given to any municipal expenditure which is not actually necessary in the national interests. The Treasury is not able to approve of in the national interests. The Treasury is not able to approve of the Council's trainway scheme, involving a capital expenditure of £250,000, and suggests the slowing down of any municipal works now in progress.

Oldham.—The Tramways Committee has agreed to a proposal of the manager that Spencer air brakes should be purchased in substitution for the air brakes now in use. The change was recommended on account of the lessened cost of maintenance The change in the case of the Spencer brakes.

Salford.— Female Conductors.— Consideration has been given by the Tramways Committee to the question of employing women as car conductors, but it is felt that the scarcity of male labour is not yet so pronounced as to make the change necessary. Alderman G. T. Jackson, general secretary of the Amalgamated Association of Tramway and Vehicle Workers, has stated that his union will not object to the employment of women during the war only, but will insist that they shall be paid the same rates as the men whom they replace. as the men whom they replace.

## TELEGRAPH and TELEPHONE NOTES.

Japan.—The Japanese Government has been inquiring into the submarine cables laid by Germany in the Far East, which amount to a length of about 4,000 miles. The main cable extends amount to a length of about 4,000 miles. The main cable extends from Kiaochan to Yap, Celebes and Guam via Shanghai. From Shanghai the lines are worked by the German-Dutch Telegraph Co., and cannot be confiscated by Japan. The line between Tsingtao and Chefoo, which extends for about 400 miles, and was operated by the German Government, was seized by Japan as a trophy of war on the fall of Tsingtao, and is now being used for official communications. The Japanese Government is considering the question of connecting the line with the newly-laid line between Shanghai and Nagasaki, with the view of facilitating telegraphic communication between Japan and China.

New telephone exchanges are being established by the Japanese Post and Telegraph Departments in the towns of Kitaku, Osaka, Rosokucho, Kanda and Tokio.

Rosokucho, Kanda and Tokio.

Wireless Telegraphists Wanted. — Wireless telegraphists between the ages of eighteen and thirty are wanted for the Royal Naval Air Service. Pay ranges from 4s. to 6s. a day, with all found. Applications should be made to the Recruiting Officer, Royal Naval Air Service, London Aerodrome, Hendon.

## CONTRACTS OPEN and CLOSED.

#### OPEN.

Aberdare.—April 6th. U.D.C. Motor-generators or converters, one H.T. switchboard and L.T. panels, and one H.T. feeder pillar. See "Official Notices" March 19th.

Aldershot.—April 20th. U.D.C. One 400-KW. D.C. turbine set, complete with surface condenser and circulating pumps, &c. One water-tube boiler with chain-grate stoker. See "Official Notices" March 26th.

May 4th Steam and other minutes to the stoken of the stoken and other minutes to the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the stoken of the

Australia.--MELBOURNE.—April 19th. of lead-covered cable, for the City Council. See "Official Notices" March 26th.

13 tons of bare hard-drawn copper cable for the April 19th.

City Council. See "Official Notices" March 26th.

May 19th. Electric signals and spare parts (Contract 28,591),
track transformers (Contract 28,359), electric train stops (Contract 28,590). all for a period of five years. Particulars at Contractors'

June 2nd. Electric lighting material for cars (Contract 28,187).

Tender box, Railway Offices, Melbourne. Particulars at Contractors Room, Spencer Street. Deposit ½ per cent. of amount of

June 15th. Four mechanically-fired boilers, for the City Council. Specifications (£1 1s.) from the City Electrical Engineer.

QUEENSLAND.—June 1st (instead of March 16th). P.M.G. Switchboard for Warwick, See "Official Notices" March 26th,

Batley.—April 6th. Electric light installation at Batley Carr Weeleyan Sunday School. Mr. E. P. Lobley, Jesmond Dene, Birkdale, Dewsbury.

April 7th. Twelve months' supply of stores for the electricity works. Mr. D. Jones, Manager.

Bray.—April 6th. U.D.C. Stores for electric light works. See "Official Notices" March 19th.

Bridgend.—April 8th. U.D.C. 400-kw. steam alternator. See "Official Notices" March 19th.

-April 12th. Corporation. Brighton.-"Official Notices" March 26th.

Bristol.—April 14th. Incandescent electric lamps (from local firms or from firms in a position to supply from local stocks), for the Docks Committee of the T.C., from May 1st to August 31st. Mr. T. A. Peace, Engineer.

London.—Southwark.—April 14th. Cable and meters, for the Borough Council. See "Official Notices" to-day.

Manchester.—April 14th. Corporation. Three 1,250-K.v.a. static transformers. See "Official Notices" to-day.

Rhondda.—April 17th. U.D.C. Installation, 83 wiring points, 88 lighting points, at the Council Offices, Pentre. See "Official Notices" to-day.

Sheffield.—April 12th. Supply of motor-van (petrol or electric) to carry one ton, for the Corporation. Specification (10s.) from the Cleansing Superintendent, Town Hall.

Whalley.--April 5th. Lathes, vices, electrical instruments, &c , for County Asylum. See "Official Notices" March 26th,

#### CLOSED.

Australia.—The following contracts have been placed:—

Melbourne City Council.—

6,000 kw. turbo-alternator, £15,111; spare parts, £1,015.—British Westinghouse E. & M. Co., Ltd.

Prahran and Malvern Tramway Trust (Victoria).—
Booster and switchgear, £930.—Noyes Bros. Pty., Ltd.

Shire of Nunawading (Victoria).—
Electric light poles, £379.—M. W. Clements.
Meters, £163.—Edison & Swan U.E.L. Co., Ltd.
Fuses.—W. T. Henley's Telegraph Works Co., Ltd.
Cables, £347.—B.I. & Helsby Cables, Ltd.

Municipal Council of Sydney; annual supplies.—
Wires and cables, schedule rates.—Henley's Telegraph Works Co., Ltd.
Fuse-boxes and fuses, £654.—Laurence & Hanson.

—Aust. Mining Standard.

Bolton.—The Electricity Committee has accepted contracts for 12 months' supplies as follows:

Casings and covers.—F. J. Webster.
Jointing material and rings.—N. Isherwood.
Trough covers.—Bolton Brick Co.

Brighton.—The B. of G. has accepted the tender of Mr. H. J. Galliers, of Brighton, for electrical fittings, at £27.

Canterbury.—The B. of G. has accepted the tender of Mr. Terry for electrical work for the ensuing half-year.

Croydon.—The tender of Messrs. Callender's Cable and Construction Co., Ltd., has been accepted by the B C. for the supply of electric cables to March 31st, 1916. This is subject to a contract providing for payment on a sliding scale based upon the market price of copper (reported to be about £70 per ton).

Ilford.—The following tenders have been accepted for

annual supplies to the Electricity Department:

Cables.—W. T. Henley's Telegraph Works Co., Ltd.

House-service fuse boxes.—J. H. Tucker & Co.; W. Lucy & Co., Ltd.

Joint boxes.—W. Lucy & Co., Ltd.

Incandescent lamps.—Cryselco, Ltd.; Electrical Manufacturing and

Supplies; London and Rugby Engineering Co., Ltd.

Meters.—Ferranti, Ltd.; British Thomson-Houston Co., Ltd.; Electrical

Apparatus Co., Ltd.

It has been decided not to enter into any contract for network boxes, but to order the boxes as required.

London.-Messrs. Napier & Kimber, Ltd., have obtained the contract for an electric lighting installation at the First Sea

Lord's residence, for H.M. Office of Works, L.C.C.—The Highways Committee recommends that the chairman and the vice-chairman of that Committee be severally authorised during the Easter recess to open any tenders that may be received in connection with the supply of cables required for the extension of the Woolwich sub-station, and to accept the most

favourable tender or tenders.

STEPNEY.—The B.C. Electricity Committee reports the purchase of 4,500 tons of coal for the electricity undertaking in various lots, at prices varying from 18s. 5d. to 27s. 6d. per ton; and also recommends that a further offer of 2,500 tons of Barnsley Bed

Top hard 1 in. nutty slack, at 19s. 6d. per ton, be accepted.

WOOLWICH.—The Electricity Committee of the Borough Council has accepted the offer of Messrs. Babcock & Wilcox, Ltd., to supply the additional shafts and uptakes for the two additional steam units, at £990.

Manchester. - Messrs. Chamberlain & Hookham, Ltd., have received a contract for tramear meters for one year from the Corporation.

#### FORTHCOMING EVENTS.

Greenock Electrical Society.—Friday, April 2nd. At 7 45 p.m. At 21, West Stewart Street, Greenock. Social meeting.

Saiford Technical and Engineering Association.—Saturday, April 3rd. At 7p.m. At Royal Technical Institute, Peel Park. Paper on "Litting Machinery," by Mr. D. Riley.

Institution of Marine Engineers.—Tuesday, April 6th. At 8 p.m. At Tower Hill, Minories, E.C. Paper on "Solid Fuel, from a Technical and Commercial Standpoint," by Mr. A. E. Battle.

North of England Institute of Mining and Mechanical Engineers.—Baturday, April 10th. At 2 p.m. At Newcastle. General Meeting.

Association of Engineers-in-Charge, --Saturday, April 10th. Social and

#### NOTES.

Geneva Water Supply.—Drinking water is raised to the city of Geneva by pumps installed in the Coulouvrenière power station on the Rhone below the city. The water is carried to these pumps by a conduit 4 ft. in diameter and 4,000 yards long terminating in Lake Geneva at a depth of nearly 50 ft. This conduit which is completely submerged, follows at first the bed of the Rhone, crosses completely submerged, follows at first the bed of the Rhone, crosses the harbour and ends at the intake strainer, 2,200 yards from the jetty. At first water flowed into the conduit in sufficient quantity by gravity alone, but recent increases in the city's water consumption have made it necessary to supplement gravitational intake, at any rate during hot weather when the lake is low. Since suction applied to the delivery end of the conduit would have involved more or less in-leakage of impure Rhone water or even mud it was decided to force water into the conduit hy a number of the conduit has a number of the conduit has a number of the conduit has a number of the conduit has a number of the conduit has a number of the conduit has a number of the conduit has a number of the conduit has a number of the conduit has a number of the conduit has a number of the conduit has a number of the conduit has a number of the conduit has a number of the conduit the conduit has a number of the conduit has a number of the conduit has a number of the conduit that the conduit has a number of the conduit that the conduit has a number of the conduit that the conduit has a number of the conduit that the conduit that the conduit that the conduit that the conduit that the conduit that the conduit that the conduit that the conduit that the conduit that the conduit that the conduit that the conduit that the conduit that the conduit that the conduit that the conduit that the conduit that the conduit that the conduit that the conduit that the conduit that the conduit that the conduit that the conduit that the conduit that the conduit that the conduit that the conduit that the conduit that the conduit that the conduit that the conduit that the conduit that the conduit that the conduit that the conduit that the conduit that the conduit that the conduit that the conduit that the conduit that the conduit that the conduit that the conduit that the conduit that the conduit that the conduit that the conduit that the conduit that the conduit that mud, it was decided to force water into the conduit by a pump installed in the lake.

For this purpose an electrically-driven centrifugal pump was erected 50 ft. away from the conduit at a point 1,700 yards from the strainer intake, and where the lake is about 13 ft. deep. The erected 50 ft. away from the conduit at a point 1,700 yards from the strainer intake, and where the lake is about 13 ft. deep. The pump suction and delivery pipes are connected in shunt to the conduit at points about 8 ft. apart between which is a valve closing automatically unless there is pressure on its up-stream face. When the pump is working this valve is closed; otherwise, the valve is open and water flows through the conduit by gravity alone. The vertical spindle centrifugal pump is direct coupled to an asynchronous motor above it, the whole being inside a sheet metal caisson 23 ft. in diameter at the base and composed of two truncated conical sections surmounted by a cylindrical section 8 ft. in diameter, which alone emerges at times of high water. Four manholes are provided in the cover, and a signal light indicates the position of the caisson by night. The caisson was assembled on the shores of the lake, towed about 2,000 ft. from the jetty, sunk by cement ballast and anchored by a ring of screw piles.

Running at 200 R.P.M. the pump discharges 14,600 gallons per minute against 10-ft. head. The squirrel-cage asynchronous motor mounted above it, in a carcass common to the two machines, develops 65 H.P., and is supplied at 2,000 volts, 40-cycles, from a special alternator in the Coulouvrenière station. This alternator generates at 2,100 volts, at 600 R.P.M., and is direct-coupled to a 105-H.P. Pelton wheel fed from the Geneva high-pressure water mains; a 5-H.P. exciter is driven in the same manner. With this arrangement operation is as simple as possible, the exciter being first started and the alternator and pump motor running up to speed together as the turbine valve is opened. Supply to the pump motor is through a three-phase cable, partly submarine; and automatic lubrication is ensured by a gear-driven pump.

Electricity in U.S. Steel Works.—Prior to 1914 the

Electricity in U.S. Steel Works.—Prior to 1914 the largest induction furnace used in the States had a capacity of only 2 tons, but last year two 20-ton furnaces were installed for steel 2 tons, but last year two 20-ton furnaces were installed for steel refining, and these are the largest of any type now used in America for this purpose. The furnaces are of the two-ring type, and use single-phase current at the exceptionally low frequency of 5 cycles per second. The motor-generator employed has 4,000 K.V.A. output at 5,000 volts, and is direct driven by a three-phase 25-cycle 2,300-volt synchronous motor. The core and coils for each furnace weigh 60 tons, and the refining process, after charging with molten metal, occupies 60 to 90 minutes. The automatic control provided in the latest types of arc furnaces is particularly interesting to practical operators in that, except during a short period after starting the furnace, constant power input is maintained at any predetermined amount. Resistance furnaces utilising heat generpredetermined amount. Resistance furnaces utilising heat generated by the passage of current through a resistor of foundry coke, with auxiliary heating from a carborundum arch throwing heat downwards on to the charge, are also provided with relay control, maintaining constant temperature automatically at anything from

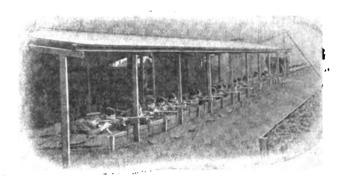

1,300 to 2,400° F.

Many modern rolling mills use electric motors exclusively for power purposes. Thus in the new works of the Bethlehem Steel Co., gas-driven alternators supply three-phase 25-cycle 6,600-volt induction motors, ranging from 350 to 3,000 H.P., and aggregating 12,000 H.P. The variable load of rolling mill machinery has proved a difficulty in the past, but the latest speed regulating equipment gives to induction motors the speed characteristics of D.C. shunt-wound machines, permitting them to carry variable load at constant speed, while retaining the mechanical strength and simplicity of the induction motor. Due to the availability of large quantities of power gas in iron and steel works, gas engine drive for electric generators is a specially tempting proposition, but one subject to well-known difficulties. Three 1,400 K.V.A.

2,300-volt 60-cycle units running at 116-R.P.M. were installed last year, and are believed to be the largest 60-cycle generators designed for gas engine drive, though 3,200 K.V.A. 25-cycle sets were previously installed at Bethlehem. The practicability of the large 60-cycle units is due to improved regulation and paralleling characteristics.

Miniature Rifle Ranges.—Few people, other than those who are actually members of Miniature Rifle Clubs, realise the enormous number of these clubs that exist in this country. the enormous number of these clubs that exist in this country. In practically every village, town and city one or more ranges were to be found before war broke out, particularly in the Midland and Northern Counties, and since then numberless other ranges have sprung into being. That practice on these ranges is of great value when the marksmen take up the more serious work of service rife shooting has been proved times without number; chiefly it is of value in accustoming the marksman to the handling of the rifle and to taking aim. and to taking aim.

The new armies in process of formation have been largely trained on the ranges built by the War Office and on private ranges. One of the Manchester Pals Battalions (the 18th Manchester Service Battalion) has been through a complete course of

WESTINGHOUSE RIFLE RANGE.

musketry on the range built by the British Westinghouse Co. in their works grounds at Trafford Park, Manchester. For many years a small range at the Westinghouse Club House has been in operation and well patronised by the members of that organisation, operation and well patronised by the members of that organisation, and this no doubt led, when war broke out, to the building of the more ambitious range, the firing point of which is shown in the accompanying illustration. No fewer than 36 men can shoot at one time on this range—10 at 25 yards and 26 at 50 yards. The cost of it, together with that of the rifles, telescopes, &c., was largely covered by the voluntary subscriptions of the employés, and a considerable part was built by them. The Westinghouse Co. gave considerable financial assistance and lent the grounds. In order to prevent any interference with recruiting, passes to shoot order to prevent any interference with recruiting, passes to shoot on this range were given only to those men who, for one reason or another, were ineligible to join His Majesty's Forces.

Legal.—PARTNERS' LIABILITY.—In the City of London Court, on March 26th, before His Honour Judge Atherley-Jones, K.O., a claim was made by Mesers, Rose Bros., 38, Beech Street, E.C., against Mr. Kohlhausen, the Hare and Hounds Hotel, East Sheen, to recover the sum of £8 18s. 4d. for electrical appliances E.C., against Mr. Kohlhausen, the Hare and Hounds Hotel, Esst Sheen, to recover the sum of £8 18s. 4d. for electrical appliances supplied to him. Mr. Clements appeared for the plaintiffs, and Mr. Coupland for the defendant. Mr. Clements said that the plaintiffs were manufacturers of electrical appliances of various kinds, and the defendant owned the Hare and Hounds Hotel at East Sheen. In 1912 defendant combined that occupation with that of an electrical business proprietor. He bought the East Sheen Electrical Co., and plaintiffs supplied all kinds of electrical appliances to him. He told plaintiffs he was the proprietor of the business and gave them bankers' references. They took them up, and they had supplied him with goods for which he had paid. Defendant was known as the East Sheen Electrical Co., and he paid his accounts from time to time with his own cheque. In 1914 the goods now sued for were supplied to the order of the East Sheen Electrical Co. Applications for payment were made, and now defendant said he had ceased to be the company at the time the goods were ordered, and the plaintiffs must look to the present proprietors. Mr. Coupland stated that the defendant had never had the goods sued for. He was not now the East Sheen Electrical Co. Mr. Clements urged that that did not matter. Mr. Coupland said that the defendant was in partnership with one Woodroff. At the outset terms of credit were arranged, and plaintiffs should not have supplied the goods now sued for. Mr. Clements added that the orders were given by someone in the service of the East Sheen Electrical Co. Defendant had held himself out as proprietor of the company and was, therefore, liable by estoppel. Judge Atherley-Jones: You say that if a man dispose of his business he must let his customers know that he is no longer controlling it? Mr. Clements said that was so. Mr. S. J. Leaver. of his business he must let his customers know that he is no longer of his business he must let his customers know that he is no longer controlling it? Mr. Clements said that was so. Mr. S. J. Leaver, plaintiffs' manager, said he did not know even now that the defendant had ceased to be the East Sheen Electrical Co. Their traveller had gone to the war. Judge Atherley-Jones: Your traveller may have had notice of the change. Mr. Clements: Notice must be sent to the firm. Witness said he never knew that the defendant and Woodruff were in partnership. Defendant brought Woodruff with him, but defendant never said that and worders must be signed by himself. Defendant said he was not an orders must be signed by himself. Defendant said he was not an electrician and he took Woodruff into partnership with him

because of his expert electrical knowledge. They took over the East Sheen Electrical Co. together, and he carefully told the plaintiffs when he called upon them with Woodruff that his (defendant's) signature was absolutely essential when orders were given for any electrical goods. He did that to safeguard himself. In Soptember, 1913, he sold the business to one Satobwell, and Woodruff had been kept on as manager. He paid all his accounts that were outstanding. The goods sued for were supplied after he left. He did not advertise the dissolution of partnership with Woodruff in the London Gazette. Judge Atherley-Jones said it was an unfortunate case in which one of two innocent parties must suffer, and the burden was to be borne by the person who was guilty of the greater negligence. Defendant was a partner with another person, and was an exploiter of electrical goods. Under a trade name he dealt with the plaintiffs. He gave his name as the owner of the business, and therefore plaintiffs must look to him for payment although it might be he had not had the goods. The law was quite clear. Defendant had held himself out as liable, and must pay the plaintiffs. Defendant could easily have relieved himself from liability by intimating to the plaintiffs: "I have ceased to be a member of this firm, and you must not look to me any longer." That was the ordinary course followed by business people, but not by the defendant. He was reluctant to do so, but he must find for the plaintiffs. The affirmative was stronger than the negative. Judgment for the plaintiffs, with coats.

Russia and Municipalisation of Electricity.—Mr. K. Y. Zagorsky, in a report presented to the Imperial Technical Society on the proposed acquisition by the town of Petrograd of the electric concerns now in operation there on the basis of concessions, said that the chief motive for proposing to municipalise electrical energy was the numerous infringements of the concessions on the part of those now holding them; such as, for example, concluding monopolistic agreements with house owners, the limitation of the use of power of other companies, the rare application of the whole-sale tariffs, and the failure to return discounts—and many other delinquencies. These and other considerations forced the town to consider the propriety of buying up the private electrical companies so as to centralise them, and thus safeguard the interests of the consumers, whilst at the same time securing an important source of revenue to the town. He held that the electrical businesses as might be the object of common industrial competition, which, in the cases mentioned, necessarily involved colossal outlays of capital to little useful purpose, when competition was allowed; whilst, on the other hand, the interests of the consumers were never consulted on their merits. He maintained that municipalisation meant cheaper current for subscribers and satisfactory financial returns to the town: and he believed that the existing tariffs to consumers could be reduced by 40 or 50 per cent., and the returns to the town be double those received from the companies now holding concessions. His report was directed chiefly to combatting the idea that the "1886 company" might be bought up, and the other companies allowed to operate independently; for, he said, these would become irritating competitors with the town.

L.C.C. Tramway Employés.—The Chief Industrial Commissioner on 17th ult. expressed the opinion that, in view of the terms of the Council's standing order, and of the facts of the case, the rate of pay for wiremen was correctly stated in the Council's list of rates of wages and hours of labour; also that the employés in the rolling-stock section, who were employed in workshops or the wiring of cars, were not entitled, under the Council's list of wages and hours, to the rate of 10½d, an hour. It was reported at Tuesday's Council meeting that the employés' representatives on the Conciliation Board had decided to abide by the Commissioner's award.

Educational.—University College Committee was received by the University Senate at their session on Wednesday last. The total number of students for the session 1913-14 was 2,206, including in the Faculty of Engineering, 134. For the current session, 1914-15, owing to the war, there has been a decline in the total number of 335; there has been an increase in the number of parttime and special students, the decline in full-time students up to the present date being 462. This decline is due to the large number of students who are taking an active part in the war. The Faculty of Engineering has been most affected, nearly all the second and third-year men having either taken commissions or enlisted. The fall in numbers will involve a decrease in fees of not less than £10,000. The report contains a summary of the work of last session, and also some particulars of the war activities of the College. The "Pro Patria" List already issued contains 665 names. A large number of Belgian Refugee Students has been received at the College, each student paying a merely nominal fee. The college staff, with the help of its friends, has provided hospitality, either partial or complete, for about 48 persons, and has raised a sum of nearly £300 to aid the students by providing money for their general expenses. All football has been suspended, and the Union Society's Athletic Ground at Perivale has been given over entirely to the purposes of a training camp, at which both students and members of the staff can receive military training. One former student, Capt. Martin Leake, who gained the Victoria Cross in the Boer War, has gained the Cross a second time "for most conspicuous bravery and devotion to duty throughout the campaign." Another student, Lieut. L. T. Despicht, has received the Military Cross "for conspicuous gallantry at Givenchy." The revenue of the College in 1913-14 was £71,567, and the expenditure £71,260. Members of the College have

already indicated their willingness to assist in meeting the deficit created by the war. The completion of the new buildings has been delayed by the war. A special effort on the part of the Equipment and Endowment Fund Committee, of which H.R.H. Prince Arthur of Connaught is president, is to be made to raise the remainder of the sum necessary for the completion of the chemical laboratories. The sum still needed for this purpose is £13 650, the greater part of which (£10 000) is required for the special equipment of a physical and electrical chemistry laboratory. The national need of improved facilities for chemical education emphasises the desirability of completing the equipment of these new laboratories.

Institution and Lecture Notes.—Sheffield Electrical Social Union.—A new society of those engaged in the electrical trade in Sheffield has been formed with the above title. Its objects will be educational as well as social, and it will be open to electrical manufacturers and contractors, members of their staffs, Corporation and works engineers and assistants. Mr. B. E. Nicholson is secretary, and Mr. A. W. Gadsby, treasurer.

Nicholson is secretary, and Mr. A. W. Gadsby, treasurer.

Diesel Engine Users' Association.—At the March meeting the question of the insurance of Diesel engines against breakdown, and the rates charged for this class of risk, was discussed. Particulars obtained in connection with a large number of Diesel engine plants showed that in many cases no insurance had been effected in consequence of the high rates charged by the insurance offices. The proportion of the amount insured to the total value of the plant concerned varied from about 18 per cent. to 66 per cent., the average being 35 per cent. of the total value of the engine. The ratio of the annual premium paid to the total value of the engine insured varied from about 1 per cent. to 3 per cent., and the ratio of the annual premium to the actual amount insured varied from about 3 per cent. to 7½ per cent. A scheme of insurance against breakdown was outlined under which members of the Association would be able to obtain advantageous terms, with a probability of a further reduction in the insurance rates later on after some experience had been obtained of the working of the scheme. One important advantage mentioned in connection with this proposal was that arrangements would be made for periodical inspections of the plant and for advice and reports by a fully qualified Diesel engine expert. At the present time the inspectors sent to make examinations by insurance companies, though thoroughly qualified as steam engineers, were usually not acquainted with the peculiarities of Diesel engines. After some discussion the proposal was referred to the Committee of the Association for further consideration. It was understood that a standard Diesel engine policy would be submitted, as well as more definite particulars as to the rates which it was proposed to charge. The next meeting of the Association is to be held on Wednesday, April 21st, when a discussion will take place on the lubrication of Diesel engines. Information and particulars concerning the Association can

Royal Institution.—The day lectures after Easter include Prof. Fredrick Soddy, two lectures: "Advances in the Study of Radio-active Bodies." Prof. J. O. Arnold, two lectures: "The Evolution of Steel: Influence on Civilisation." Dr. A. W. Porter, two lectures: "Advances in General Physics." Prof. J. A. Fleming, two lectures: "Photo-Electricity" (The Tyndall Lectures).

Institution of Electrical Engineers.—The following are the Council's nominations for election to the Council for the year commencing October 1st, 1915:—

President (one vacancy).-C. P. Sparks.

Vice-Presidents (two vacancies) .-

Dr. A. Russell. R. T. Smith.

Honorary Treasurer (one vacancy).-R. Hammond.

Ordinary Members of Council.—Members (five vacancies).—

W. A. Chamen.
H. Dickinson.
H. W. Firth.
Prof. T. Mather, F.B.S.
H. F. Proctor.
G. S. Ram.
W. Slingo.
A. H. Walton.

Associates (one vacancy).-J. Hunter Gray.

The following members remain in office:-

Vice-Presidents-

J. S. Highfield. C. H. Wordingham.

Ordinary Members of Council—

Ordinary Members of Council—

F. E. Berry.
R. A. Chattock.
J. Christie.
E. Russell Clarke.
Major E. O. Henrici, R.E.
Prof. B. Hopkinson, F.R.S.

A. W. Martin.
A. M. Ogilvie, C.B.
G. W. Partridge.
W. H. Patchell.
R. J. Wallis-Jones.
W. B. Woodhouse.

It was the unanimous desire of the Council to nominate the President, Sir John Snell, for a second year of office; but the President, while thanking the Council for the honour, expressed his regret that for reasons of health, and on account of the claims of his professional work, he would be unable to accept nomination

Electrical Heating and Cooking Apparatus.—In a paper which Mr. Stanley M. Hills, A.M.I.E.E., is reading before the Junior Institution of Engineers on Monday, April 12th, he proposes to give a description of the various radiators, convectors, &c., the heating of rooms and offices, hotplates, grills, ovens, energy consumption of a cooker, utensils, and running costs. Tickets can be had from Mr. A. Clifford Swales, secretary, 39, Victoria Street. Westminster.

Delays and Discounts.—At Church Police Court (Lancs.) last week, James Clayton, landlord of the Queen's Hotel, Church, was summoned by the Accrington electricity department Onurch, was summoned by the Addring on electricity department for non-payment of an account for electricity. It was stated that the amount in question was 13s. 9d., the balance of an account for electricity, for the quarter ending September last. Defendant had deducted this amount for discount to which he was not entitled. The last date for discount was November 23rd, and the cheque was received on the afternoon of November 24th, and plaintiffs contended that it was evident that the cheque had not been posted until the morning of the 24th. Defendant admitted that he could not prove that he posted the cheque on the 28rd. An order for payment was made, with costs.

Municipal Competition.—Mr. R. C. Walsham, speaking as president of the National Chamber of Trade at Lancaster, said the sale of electrical fittings by municipalities was interfering with the rights of private traders.

1st London Engineers.-New Field and Signal Com-181 London Engineers.—New Field and Signal Companies (312 and 240 men respectively) are again being raised by the 1st London Divisional Engineers (T.F.), as three of their units have already gone abroad on active service. Smart intelligent men are wanted—for the field companies, men connected with the building and constructional iron trades, all-round electricians, &c., and for the signal companies, young men of good education, especially telegraphists, electricians, instrument makers and telephone operators, all of whom are taught to ride. The work is very interesting, and the pay is considerably higher than in most other arms of the service. Application should be made to the headarms of the service. Application should be made to the head-quarters, 10, Victoria Park Square, Bethnal Green, or to the branch recruiting office, Labour Exchange, Edgware Road.—Standard.

A Siemens Social.—The Siemens Dalston Miniature A Siemens Social.—The Siemens Dalston Miniature Rifie Club has been well supported during the past four years, and the present season's membership forms the record since its inception. Some 23 past members of the Club are now serving with the Forces, which makes the present membership of the Club all the more satisfactory. A Social Evening was held at Mozart House on Friday, March 26th, under the auspices of the Club, and a party of about 150 club members and their friends experienced a very enjoyable evening. Mr. A. B. Holmes distributed the medals and spoons won during the current half-season. Vocal and instrumental items were interlarded with dancing, and an extremely long programme was put through between 7.30 and 12 p.m. The arrangements were in the hands of the Club Committee, and Mr. F. S. Dennison acted as hon. M.C. 12 p.m. The arrangements were in the hands mittee, and Mr. F. S. Dennison acted as hon. M.C.

Private Arrangement.—W. A. Boissier, electrical engineer, East Street, Derby.—The creditors interested herein were called together recently, when a statement of affairs was presented showing liabilities of £1,956, of which £751 was due to the trade, and £1,205 to cash creditors. The assets were estimated to realise £456, from which had to be deducted £6 5s, for preferential claims, leaving net resets of £450, or a deficiency of £1,506. The debtor, who was only 24 years old, commenced business in April, 1910. He had little or no capital of his own, but his father-in-law advanced him various amounts. The debtor had prepared rough trading accounts at various dates and they had prepared rough trading accounts at various dates, and they showed that a profit was made in the business. An offer was made of a cash composition of 6s. 8d. in the £. An increased offer was pressed for, and eventually 7s. 6d. in the £ was offered, and was accepted by the creditors.

Appointments Vacant. — Electrician (£80 +), for Clonmel District Lunstic Asylum; switchboard attendant (27s. 6d.), for Borough of Lancaster. Particulars are given in our advertisement pages to-day.

The I.M.E.A. Development Committee. meeting of this Committee held on March 12th, reports were received from the several Sub-Committees, whose operations have to a considerable extent been interfered with by the difficult conditions existing at the present time. The question of the production of printed publicity matter received attention.

The possibilities and limitations.

The possibilities and limitations under which municipal electric supply undertakings work to-day were dealt with at some length for the benefit of the considerable number of co-opted members who were present, and who offered suggestions and assistance which were much appreciated.

It is anticipated that some more or less workable scheme for carrying on publicity work by means of printed matter, Press advertisements, &c., will shortly be brought before the full

Mr. H. C. Palmer (of the General Electric Co.) and Mr. L. G.

Tate were co-opted members of the Publicity Sub-Committee.
Further discussion arose around the work of the Sub-Committees on "Domestic Appliances" and "Electrical Installations" (Hon. Secs. Mesers. Roles and Allen); and proposals from these gentlemen were considered.

It was understood that these and other similar Sub-Committees would probably be able to carry on a very considerable amount of valuable work of a definite character in the direction of col-lating and analysing the mass of information at present existing amongst engineers and manufacturers on the subjects dealt with by the Committees, and that the results of such investiga-tions would be available to the full Committee, and also would form useful, matter for the guidance of the operations of the Publicity Committee. A further question of making such information generally available for manufacturers, and the information generally available for manufacturers and the electricity-using public received consideration, and will be referred to again later.

A Question of Means.—In Croydon Police Court on Monday the question of the means of Norman D. Frost, a canvass in the employment of a London electrical supply company, was being discussed so as to enable the Bench to arrive at a sum being discussed so as to enable the Bench to arrive at a sum to be allowed his wife under a separation order, he being the defendant. He said he received £2 2s. weekly and travelling expenses, the maximum being 6s. weekly. There was no commission. His duty was to advise people about electric light installations. Complainant's solicitor: Have you borrowed money from electricians? Defendant: Yes. The solicitor: And you have never paid it back? Defendant: No, because I have not been requested to. The solicitor: But you know perfectly well this money is lent? Defendant: Yes, but they never ask it back. Pressed further, defendant said the last sum of the kind received was about £2. fendant said the last sum of the kind received was about £2. He could not give the exact date of the transaction; it was sometime before Christmas. The clerk: Did you give an I.O.U. for it? Defendant: I gave nothing for it. The solicitor: How much a year did you get in loans of this sort? Defendant: At the outside, taking the year right through, I should say £6; that is the best I have done. Defendant admitted having borrowed from other tradesmen not electricians but denied that it was within his power to give them dant admitted having borrowed from other tradesmen not electricians, but denied that it was within his power to give them work. The Solicitor: Do you say, "Go to Mr. So-and-So for your work; he is the finest electrician in the town?" and then go yourself to Mr. So-and-So and say, "Lend me a fiver?" Defendant: I do nothing of the kind. The Solicitor: Is it a fact that you are able to put work in the way of electricians? Defendant: If I cared I could put work in the way of a great many people. Defendant was ordered to pay his wife 15s. a week, and the solicitor hoped his employers would come to hear of his statements.

Fatality —LANGLEY —On March 24th at the works of

Fatality.—LANGLEY.—On March 24th, at the works of Mesers. Albright & Wilson, at Langley, James Wilcox (19), who was engaged on a railway siding which runs into the works, was found lying on the floor and clutching a "live" electric wire which passed over the spot into an adjoining factory. Dr. Broughton was summoned, and attempts were made to restore animation, but without success. Another man who released animation, but without success. Another man who released deceased from the wire experienced a shock, but quickly recovered. It is surmised that while deceased was throwing a cover over the truck on which he was standing he slipped, and in falling clutched the wire to save himself.

#### OUR PERSONAL COLUMN.

The Editors invite electrical engineers, whether connected with the technical or the commercial side of the profession and industry, also electric tramway and railway officials, to keep readers of the ELECTRICAL REVIEW posted as to their movements.

Station Officials.—The York Corporation Central tentral Station Umicials.—Ine fork Corporation has granted increases of salary to the following employés in the electricity department:—Mr. S. Spofforth, Mr. Petrekin (draughteman), Mr. E. M. Pearson (mains superintendent).

Mr. E. W. Martin, assistant distribution engineer in the Woolwich electricity department, has been promoted to the second

class of the engineering staff in that department, and his salary has been increased to the maximum of such class, viz., £150 per

The Ilford Council has been recommended to increase the salarie of Mr. R. F. WINDETT, meter superintendent, and Mr. E. W. FOWEBAKER, fourth charge engineer.

MR. WILLIAM CHAMBERLAIN, mains superintendent engineer in the Oldham Corporation electricity department, was married last week to Miss Lilian Hood, daughter of the late Ald. Hood, a former

Mayor of the borough.

MR. F. SPINK, Works Superintendent of the Worksop Electricity Works, has recently resigned his appointment, and has entered the Navy, as an Electrical Artificer, for the period of hostilities.

Tramway Officials.—Mr. Dugdale, the general manager of the Oldham Corporation tramways, who has been ill for some time, is now very much improved in health.

Dover Tramways Committee has appointed Mr. Bond, of the Colchester tramway staff, as depot foreman.

General.—The marriage took place at St. Bartholomew's Church, Ruswarp. on March 22nd, of Mr. WILLIAM HENRY ATKIN, electrical engineer, of South Bank, and Miss Edith Porritt youngest daughter of Mr. William Porritt, of Ruswarp.

The Special Committee of the L.C.C. on London Electricity Committee recommends that Mr. G. M. GILLETT, Mr. H. H. GORDON and the HON. GILBERT JOHNSTONE be appointed members of that

Obituary.—We regret to learn that Mr. MATTHEW THOMAS MEDWAY, founder and head of the Medway's Safety Lift Co., Deptford, S.E., died at Brockley on March 22nd. He was 65

PROF. HENRY ROBINSON .--We regret to learn that Prof. Henry Robinson, M.Inst C.E., Emeritus Professor of Civil Engineering at King's College, London, passed away in London on March 24th. In the earlier days of electricity supply the late Professor was prominently associated with the design and installation of a number of undertakings in London and the provinces

Wills.—The late Dr. Anthony Traill, Provost of Trinity College, Dublin, left £6,779.

The late MB. J. F. ALBRIGHT left £32,601 net and £33,854 gross personalty.

#### NEW COMPANIES REGISTERED.

Hubert D. Carter, Ltd. (139,734).—This company was registered on March 23rd, with a capital of £5,000 in £1 shares (2,000 7 per cent. cum. pref.) to carry on the business of gas, electrical, motor and hot water engineers and fitters, lighting contractors, plumbers, manufacturers of wire, screws, nails, rivets, nuts, bolts and electrical equipment of all kinds, to acquire the business carried on by H. D. Carter at Colwyn Bay. The subscribers (with one share each) are: H. D. Carter, Crosley House, Colwyn Bay, electrical engineer; C. L. Williams, Bolton Villa, Colwyn Bay, secretary; W. E. Buckley, Beech House, Colwyn Bay, gent. Private company. The number of directors is not to be less than two or more than five; the first are H. D. Carter (permanent managing director, special qualification 50 shares) and others to be appointed by the subscribers. Qualification of directors 10 shares. Remuneration of managing director, £150 per annum and a percentage of the profits. Solicitor, E. A. Crabbe, Cronhaulog Chambers, Abergele Road, Colwyn Bay. Secretary, H. D. Carter. Registered Office: Sea View Terrace, Colwyn Bay.

Cark and District Electric Supply Co., Ltd. (139,728).—
This company was registered on March 23rd, with a capital of £9.000 in £1 shares (1.500 6 per cent. cum. pref.), to carry on at Cark, Flookburgh, Allithwaite and adjoining district the business of an electric light supply company in all its branches. The subscribers (with one share each) are: C. H. Best, 72, Market Street, Bradford, incorporated accountant; G. Dickinson, Cark Mills, Cark-in-Cartmel, corn merchant; F. Wilkinson, Bankfield, Allithwaite, collery agent. Private company. The number of directors is not to be less than three or more than five; the subscribers are to appoint the first. When there are only three directors, two shall be holders of ordinary and one the holder of preference shares; when there are five, three shall be holders of ordinary and two the holders of preference shares; when there are five, three shall be holders of ordinary and two the holders of preference shares. Qualification £25. Remuneration as fixed by the company. Solicitor, F. W. Poole, Ulverston, Lancs.

Roto Engineering Co. (Bradford), Ltd. (139,737).—This company was registered on March 23rd, with a capital of £1,000 in £1 shares, to carry on the business of electrical, mechanical and ventilating engineers, merchants, manufacturers of rotary pumps, oil cabinets, filters and other appliances, steam, hydraulic, pneumatic or other engines, etc. The subscribers (with one share each) are: H. Hornby, § Clarendon Street, Bradford, iron merchant; F. Laycock, 82, Beech Grove, Lidget Green, Bradford, managing clerk. Private company. The number of directors is not to be less than two or more than 5; the subscribers are to appoint the first. Qualification, 50 shares. Remuneration as fixed by the company. Solicitor, A. V. Hammond, Dale Street Chambers, Bradford. Registered office: Borough Mills, Bradford.

# OFFICIAL RETURNS OF ELECTRICAL COMPANIES.

Rhondda Tramways Co., Ltd.—Particulars of £250,000 debentures, created by resolutions of March 13th, 1911, November 8th, 1912, and February 4th, 1915, and secured by trust deeds dated March 24th, 1911, November 13th, 1912, and March 11th, 1915, filed pursuant to Section 33 (3) of the Companies' (Consolidation) Act, 1908, the amount of the present issue being £10.000. Property charged: The company's undertaking and property present and future, including uncalled capital and tramways and right of user or same, and lands with generating station and other premises thereon, together with equipment of tramways, and all purchase moneys to be received from Rhondda Urban District Council, etc. Trustees: Law Debenture Corporation, Ltd., 41, Threadneedle Street, E.C.

Corona Lamp Works, Ltd.—Issue on 27th February, 1915, of £4,350 debentures, part of a series of which particulars have already been filed.

Newcastle-upon-Tyne Electric Supply Co., Ltd.—Charge, as substituted security, dated March 4th, 1915 (supplemental to trust deed dated October 16th, 1913, and acknowledgment of indebtedness dated November 16th, 1914, securing £500,000 deb, stock). Property charged: All shares in capital of Carville Site and Power Co., Ltd., which may during the continuance of the security constituted by the trust deed be acquired by the company. Trustees: Law Debenture Corporation, Ltd., 41, Threadneedle Street, E.C.

Naylorgraph, Ltd.—Two debentures, dated 13th March, 1915, to secure £576 and £100 respectively charged on the company's undertaking and property, present and future, including uncalled capital, if any, subject to prior debs. Holders: J. M. Hunt, Fairlawn, Park Road, Southborough, and J. P. Naylor, 57, Croxted Road, Dulwich, S.E.

### CITY NOTES.

#### North Metropolitan Electric Power Supply Co., Ltd.

Mr. E. Garcke presided on March 25th over the annual meeting, held at Electrical Federation Offices, Kingsway. He said that last year they sold 36,800,000 units of electricity, an increase of 2,400,000, or about 7 per cent. The increase would have been much larger but for the outbreak of war, for in the first half of the year the increase was 2,800,000 units, but in the second half there was a diminution of over 400,000 units, and that notwithstanding that the second half of the year was usually better for the electricity supply business than the first half, especially where current was supplied for working tramways. The North Metropolitan Electric Tramways, for which they supplied current, ran fewer car miles and consequently consumed less energy, and the various power users in the district also reduced their consumption. Although the increase in the volume of business was less than the normal increase in previous years, they had obtained a revenue of £173,000 compared with £164,000 for 1913, and had made over £3,000 more profit. He thought that, having regard to all the cir-

cumstances, the result of the year's working must be considered satisfactory, especially as several items of expenditure had increased owing to rises in prices. They had had to spend over £50,000 on coal, compared with about £47,000 in 1913. The balance to net revenue was £92,791. After providing for mortgage, loan and debenture interest and transferring £2,000 sadered sausactory, corresponding to rises in prices. They had had to spend over £50,000 on coal, compared with about £47,000 in 1913. The balance to not revenue was £92,791. After providing for mortgage, loan and debenture interest and transferring £2,000 to the reserve to secure the redemption of the debentures, and placing £1,624 to the depreciation account—raising it to £100,000, writing off the whole of the preliminary expenses, amounting to £14,941, there was sufficient to pay the 6 per cent. cumulative preference dividend for the year, the same dividend on the ordinary shares as a year ago, leaving £4,676 to be carried forward, compared with only £1,054 brought in from the preceding year. They had thought it wise to write off the whole of the preliminary expenses instead of further increasing the depreciation reserve, seeing that the depreciation fund now amounted to £100,000, which they considered an adequate reserve for the time. They had also thought it wise to earry forward a larger amount of undivided profit in view of the general uncertainty as regarded the profit which might be earned during the current year. The dividend on the preference shares had absorbed £5,000 more than in 1913, which arose in consequence of their having issued £100,000 additional preference share capital during the past year in order to provide for capital expenditure rendered necessary by the extension of their power bouses and the laying of a main trunk cable from their Willesden power house, through Wembley and Pinner, where they were now supplying electricity in bulk for lighting purposes. The capital expenditure during the year had amounted to £83,295. The shareholders would be interested to know that the company's business continued to develop satisfactorily. They had recently made several contracts with new power users, and the general manager was in communication with several other factories for the supply of electricity. The electricity distribution business of their subsidiary company was also progressing satisfac -the North Metropolitan Electrical Power Distribution Co.—were now serving in either the Army or the Navy, and included among the officers was Mr. Boves, their secretary. Those remaining at home were subscribing to a joint fund which the associated tube and tramway companies had inaugurated for the purpose of providing assistance for the dependents of those employés who had joined the Colours. The company had also joined in the contributions made to the various war funds by the British Electrical Federation.

Sir Envery Survey seconded the resolution and the report

Sir Ernest Spencer seconded the resolution and the report was adopted.

#### London and Suburban Traction Co., Ltd.

The Rt. Hon. C. B. Stuart Wortley, K.C., M.P., presided on Friday last over the annual meeting held at the Holborn Restaurant. The Chairman said that in the case of the tramway and omnibus companies in which they were interested, their total traffic receipts amounted to £1,303,900 odd, against £1,152,494 in 1913. The passengers carried were 246,800,000, against 218,900,000. The electricity supply companies in which they were interested sold a total of 39,510,000 units in 1914, as compared with 36,904,000 in 1913. Their total income from their holdings in the various subsidiary companies was £107,884, plus £10,593 for interest on money which they had lent to the companies. That compared with £98,825 and £3,309 respectively in the previous year. Including sundry receipts the total revenue was £118,579, against £105,370 in 1913. On the other hand, the administrative and general expenses had amounted to £2,077, against £1,980. They had do to find for interest on debenture stocks, original and new, £18,695, against £5,094; and for interest and other moneys borrowed £5,555, against £7,013. Including the item of £6,200 put aside as a sinking fund for the redemption of the 5 per cent. debenture stock, the total expenses for 1914

amounted to £34,953, against £17,018 for 1913. The result was that they had been able to pay the full dividend on the cumulative preference shares amounting to £30,110, as well as £9,226 for dividend on the ordinary shares for the first half of the year at the rate of 1 per cent. per annum, and carrying forward £2,886, against £8,597 last year. The shareholders would see that in the first half of 1914 they had a fair prospect of realising the hopeful anticipations in which he indulged at the last meeting. It was in the early days of July and before the outbreak of war that they declared the interim dividend. The final results for the year showed that though the effect of war on the various subsidiary companies had undoubtedly been adverse, it might well have been worse than it was. It had certainly removed from the streets a large number of omnibuses which competed with the tramways of many of their subsidiary companies, and to that extent it had helped them. It was, of course, impossible to say what their experiences would be during the remainder of the war, but he thought they were justified in hoping that a return to peace conditions would mean for them a return to the modest kind of prosperity which the first half of 1914 seemed to promise. Out of 4,186 employés in the associated companies no less than 1,110 had joined the Forces, which was 24 per cent. of the whole. The company was throwing in its lot with the T.O.T. Mutual Aid Fund, which was looking after the dependents not only of the underground railway and tramway men but of the men in power houses as well who had joined the Colours.

Mr. E. Garcke seconded the motion. Colours

Mr. E. Garcke seconded the motion.

Replying to a shareholder, the Charrman said he was given to understand that the chairmen of subsidiary companies were satisfied that a sufficient amount had been set aside for depreciation in regard to each concern.

The report was adopted.

#### Liverpool District Lighting Co., Ltd.

Liverpool District Lighting Co., Ltd.

The annual meeting was held on March 24th, Mr. W. A. Cookson presiding. The Secretary read a statement from Mr. Charles McLaren (the Chairman, who was indisposed) which said that the war had retarded business during the second half of the year, and instead of an estimated increase of 50,000 units sold they had increased the sale by only 31,279 units, which, considering all things, was a very creditable result. The profits, which had increased by £744, amounted to £5,422, which, after deducting the interest paid on bank overdraft, was exactly equal to 8 per cent. of the ordinary capital. They had had to pay a higher rate of interest, more income tax, and they had also paid the wages of their employés who had joined the Colours, who numbered one-third of the staff. They did not anticipate any serious capital expenditure during the present year. By an agreement with the Hightown Gas & Electricity Co. they were now supplying them in bulk for distribution and sale in their own district of Hightown, and in this way they were supplying a large military camp at Sniggery Woods, and also the battery at Hightown. They were also supplying by arrangement electricity to another camp situated at Thornton, about 220 yds. beyond their boundary. That would make up for the economies tractised by their existing consumers, but they could not look forward to any substantial increase of business during 1915. They had always been handicapped by want of coal storage tunkers capable of holding 500 or 600 tons, and consequently were apt to be hit by strikes of workmen, and now by the war. Their engineer was preparing a report and plans suitable for coal storage bunkers, and if they found it was in any war. Their engineer was preparing a report and plans suitable for coal storage bunkers, and if they found it was in any way possible to erect them at a reasonable cost they intended to make themselves independent of the fluctuations in the coal trade. Doubtless many shareholders would think that having made profits equal to 8 per cent. of the capital a dividend of 5 per cent. might be paid, but the directors after due consideration decided that this time of national crisis was not the time to increase dividends.

Cleveland and Durham Electric Power, Ltd.-The directors report that during 1914 the capital expenditure on works was £14,915. The gross profits, which have been adversely affected by the war, amounted to £36,839. After providing for debenture interest the net profit is £16,826, plus £8,799, brought forward. The directors propose a dividend of 4 per cent. on the preference shares, transferring to depreciation and renewals account £3,000, reducing expenses of issue of debentures by £1,000, and carrying forward £8,277.

Wm. Beardmore & Co., Ltd.—The Times states that the profit for 1914 amounted to £219,142 (against £164 236), and £186,947 was brought forward. The directors place £50,000 to special preference dividend reserve, and, after paving the year's dividend on the preference shares, recommend a 5 per cent, dividend on the ordinary shares, leaving £193,089 to carry forward. For the preceding year the dividend was the same.

Vickers, Ltd.—In consequence of the great pressure due to the war, it has been found impossible to complete the yearly accounts for presentation at the usual date. In the meantime, the final dividend of 5 per cent. on the preferred 5 per cent. stock and on the 5 per cent. preference shares have been paid.

Altrincham Electric Supply, Ltd.—We have now received a copy of the report which was adopted at the annual meeting held last week. There were 88 new installations connected to the mains during 1914. The accounts showed a profit of £8,349. Including £2,776 brought forward the amount available for distribution was £9,612. Balance of preferred dividend required £1,059, there was put to general reserve £500, and to depreciation of machinery account £1,500, leaving £5,503, out of which a dividend of 10s, per share upon the deferred shares. Mr. F. O. Arnold has been elected a director. We understand that the progress of the company was arrested by the war. For the first month or so of war the power loads showed a diminution owing to short time in the factories, and when Government work was freely given out towards the end of the year there was a lack of men in the work hops, and this fact then and still prevented the company from resping the benefit that would have ensued from overtime. The actual output was less than in 1913 owing to consumers household economies and the shorter hours on power loads. Working expenses were, however, reduced in spite of an increase of 11 per cent. in price of coal. It is interesting to learn from Mr. G. H. Fawous, the engineer and manager, that he has one large farm on the mains for both power and lighting, and one more at least is coming on within the next few weeks. Altrincham Electric Supply, Ltd.—We have now least is coming on within the next few weeks.

Newmarket Electric Light Co., Ltd.—The annual meeting was held recently, Mr. F. E. Gripper presiding. The directors' report stated that during 1914 the equivalent of 1,015 33-watt lamps had been connected, making the total 30,744 lamps. The profit on the year's working, with £146 brought forward, amounted to £2,464, and after deducting £733, debenture and other interest, £1,731 remained available. The directors recommended a dividend of 3½ per cent., £650 being carried to reserve for renewal of plant, leaving £151 to be carried forward. Mr. Gripper said that the dividend recommended was ½ per cent. less than last year. But for the war they would have had a record year. Receipts from sales of current had fallen off; also receipts from wiring account by £145. Expenditure had increased by £40, this being mainly due to rates and taxes. The balance available for distribution was less by £228 than last year. The report was adopted. adopted.

American Telephone and Telegraph Co.—The report states that the net earnings were \$40,557,977, or approximately the same as in the previous year. The interest charges were \$8,223,163 and the dividends at the regular rate of 3 per cent, per annum were \$27,572,674. Of the resulting balance there was carried to reserves \$2,500,000 and to surplus \$2,262,139. At the end of the year the number of stations which constituted the system in the United States was 8,648,993, an increase of 515,976, including 168,177 connecting stations; 2,885,985 of these were operated by local, co-operative and rural independent companies or associations having sub-licence or connection contracts, so-called connecting companies. The Bell telephone toll lines of the United States now reach 70,000 places, from substantially all of which messages can be telephoned to the nearest telegraph office.—
Financial Times.

Companies Struck Off the Register.—The following companies have been struck off the Register, and are accordingly dissolved :-

British Tungsten Metals Syndicate.
Electrical Regulators and Economisers.
Frank Suter & Co.
Go. witz & Co. Aluminium Fabrik Weilar (Bhon) Aktiengesellschaft.
Indestructible Acoumplators.
Indicating Fuse and General Manufacturing Co.
International Electric Transport and Enterprise Co., of Alsace
Lorraine. Lorentine:
Kellogg Manufacturing Co. (Europe).
Leeds and Bradford District Electric Railways.
Reis Oil Fuel, Gas Producer and Burner.
Scientific Illumination.
Telephone Disinfecting Co.

Clyde Valley Electrical Power Co.—The report for the half-year ended December 31st last states that the profit amounts to £37,662, plus £37,662 brought forward. After payment of the dividends on preference shares to October 31st, 1914, amounting to £9,000, and after adjusting interest and transferring £12,500 to contingency fund for depreciation, &c., there remains £33,826. The directors recommend that £3,290 be transferred to special reserve, £10,000 applied in writing down cost of Acts, 1901, 1904 and 1912, and £9,000 provided for the dividend on preference shares to April 30th, 1915, leaving £11,535 to be carried forward.

Gateshead and District Tramways Co., Ltd.-A dividend at the rate of 6 per cent, per annum, and a bonus of 64, per share (together 12s, per share), on the ordinary shares, making 9 per cent, for the year, are announced.

Stock Exchange Notice.—The Treasury has authorised dealings in the following securities:—

Bombay Electric Supply and Tramways Co., Ltd.—12,000 "new" ordinary shares of £10 each.

Howard & Bullough, Ltd.—An interim dividend at the rate of 10 per cent. per annum, less income tax, on the ordinary shares is announced for the past quarter.

Company Meetings.—The annual meetings of the British Westinghouse Electric and Manufacturing Co., Ltd., and the Brush Electrical Engineering Co., Ltd., were held on Monday in London. We shall report the proceedings in our next issue.

#### United Tramways, Ltd.

MR. W. M. Acworth presided, on Friday last, over the annual meeting held at Electrical Federation Offices, Kingsway. The CHAIRMAN said that the shareholders outside the London and Suburban Traction Co. only held about 3 per cent. of the Suburban Traction Co. only held about 3 per cent. of the stock. The work of the reconstruction of the Hammersmith lines had been completed, bringing up the expenditure to £62.000. Pending the completion and sale of those lines to the L.C.C., they were paying interest and sinking fund charges upon the amount advanced for the reconstruction, £12,500 had been appropriated to reserve for reconstruction and renewals out of profits, while £29,000 had been charged against that fund. That amount was almost wholly represented by the reconstruction of the line from Brentford to Hounslow, which was originally opened in 1901. After allowing for that appropriation there remained a balance of £8,142, of which £6,250 had been distributed in payment of a dividend at the rate of per cent. on the preference shares last July. The traffic receipts, amounting to £316,000, showed a decrease of over and been distributed in payment of a dividend at the rate of a per cent. on the preference shares last July. The traffic receints, amounting to £316,000, showed a decrease of over £11,700; the car mileage run was some 410,000 miles less than the previous year, and the receipts per car mile showed a decrease of .08d. In the first seven months of the year the passenger receipts were £2,243 in excess of those for the corresponding periods and the receipts per car mile showed and the receipts per car mile showed and the passenger receipts were £2,243 in excess of those for the corresponding periods and the receipts per car mile showed and the receipts periods and the receipts per car mile showed and the receipts periods and the receipts periods and the receipts periods are the correspondent to the corresponding periods and the receipts periods are the correspondent to the correspondent periods are the correspondent to the correspondent periods are the correspondent to the correspondent periods are the correspondent to the correspondent periods are the correspondent to the correspondent periods are the correspondent periods are the correspondent periods are the correspondent periods are the correspondent periods are the correspondent periods are the correspondent periods are the correspondent periods are the correspondent periods are the correspondent periods are the correspondent periods are the correspondent periods are the correspondent periods are the correspondent periods are the correspondent periods are the correspondent periods are the correspondent periods are the correspondent periods are the correspondent periods are the correspondent periods are the correspondent periods are the correspondent periods are the correspondent periods are the correspondent periods are the correspondent periods are the correspondent periods are the correspondent periods are the correspondent periods are the correspondent periods are the correspondent periods are the correspondent periods are the correspondent periods are the c decrease of .08d. In the first seven months of the year the passenger receipts were £2.243 in excess of those for the corresponding period, and the receipts per car mile showed an increase of .17d. At the end of the year, however, that increase in receipts had been turned into a decrease of £11,793. At the commencement of August they were compelled to reduce their services very considerably owing to the number of motormen and conductors who were called up as Reservists. Over the per cent. of the staff were now serving with the Army of Newy. In addition, a considerable number had since the war consisted in the new forces, and, although new men had been taken on, they were still considerably below their normal number. Originally they had 825 motormen and conductors; now they only had 668. Apart from the reduced services, the receipts decreased owing to the earlier closing of the publications and the decreased street lighting. He said last vear that he thought their affairs had touched bottom, and their traffics for the first half of 1914 showed that but for the war they would have compared favourably with 1913. Unfortunately, the working expenses in 1914 did not decrease in proportion to the car mileage. With the exception of the item of running expenses, the working expenses remained more or less constant, although the car mileage had considerably decreased. The company had ioined in the T.O.T. Mutual Aid Fund for the purpose of giving help to the dependents of those of the stoff who had ioined the Colours. They had done what they could to encourage increased traffic by issuing cheap farcs for children, and they had obtained powers to run trailer cars and carry passengers in excess of the authorised number at times when there was a rush of traffic. cars and carry passengers in excess of the authorised number at times when there was a rush of traffic.

Lord KNUTSFORD seconded the motion and the report was

adopted.

#### Metropolitan Electric Tramways. Ltd.

Me. E. Garcke presided on Friday last week over the annual meeting, held at Electrical Federation Offices, Kingsway. The Chairman said that in the early part of last year they had reason to hope that the results of the year's working would be materially better than was shown by the accounts. Up to the lat of August the traffic receipts were £7,000 greater than those for the corresponding period of 1913, and the receipts per car mile showed an increase of £2d. By the end of 1914, however, this increase in the receipts had been turned into a decrease of £8,500. At the commencement of August the company was compelled to reduce the services very considerably, owing to the number of motormen and conductors who, as Reservists, were recalled to the Colours, and 25 per cent. of the total staff were now serving with the Army and Navy. Apart from the reduced services, the receipts decreased owing to the earlier closing of shops, and because of the restricted street lighting. There was now but little traffic after about 10 o'clock at night in the districts served by the company's tramways. Unfortunately, the working expenses did not decrease in direct proportion to the reduction of the receipts, for, with the exception of the expenditure on electrical power for, with the exception of the expenditure on electrical power and on wages account, the item of working expenses remained and on wages account, the term of working expenses remained more or less constant irrespective of the car mileage, and even the wages bill had not been reduced in proportion to the reduced-services, because during the past year they conceded the men an increase in the rate of pay. A matter of some interest to the public in connection with the traffic arrangements of the company was the extension of through sorvices between the company was the extension of through services between the tramways operated by the company and the tramways of the London County Council. Since September last through ices of cars had been operated between Barnet and Euston services of cars had been operated between Barnet and Euston and Moorgate Street via the Archway Road. Passengers on the Barnet line could also now book through to Charing Cross from North Finchley via the Highgate Tube Railway. At Stamford Hill the company and the L.C.C. had agreed to issue 1d. transfer tickets between each other's systems. Through booking arrangements were also about to be established at Golders Green between the company's Finchley Road line and the Hampstead Tube Railway as far as Charing Cross, and at Sambha Lane between the company's line from Harles. and at Scrubbs Lane between the company's line from Harlesden and the L.O.O tramways as far as Hammersmith. Cheap tickets were now issued to children under fourteen years of

age on week-days between the hours of 8.30 a.m. and 5.30 p.m. It afforded the directors much satisfaction to be able to give the public these improved travelling facilities, although that company did not derive much pecuniary benefit from them. The accounts did not call for much explanation. They had expended on capital account during the year £13,263. They had had to increase the suspense account by about £2,000 in respect of interest and expenses in connection with the Watford and Bushey undertaking which had not been £2,000 in respect of interest and expenses in connection with the Watford and Bushey undertaking, which had not been proceeded with, because they decided that the district could be better serve by onnibuses. They had increased the reconstruction and renewals fund investment by about £30,000, and a full list of the investments in which the fund of £138,893 was invested was now appended to the report. It was very nearly eleven years since the first of their lines was opened for electrical working. During that period they had built up large reserves for the purpose of providing for the renewal of the lines, as they were worn out, and it was a very satisfactory feature that the lines had all been maintained in excellent condition, so far, almost entirely out of revenue, and that factory feature that the lines had all been maintained in excellent condition, so far, almost entirely out of revenue, and that the large fund which they had accumulated was available to meet any abnormally heavy expenditure on track renewals which might be necessary in future. About 95 per cent. of the whole of the share capital of this company was now held by the London and Suburban Traction Co., Ltd., and only about 8 per cent. of the preference and about 2 per cent. of the ordinary shares were in the hands of other shareholders. The policy of the company was, therefore, now directed by the board of the London and Suburban Traction Co., Ltd. On former occasions he had explained that since the control of this company had passed over to the London and Suburban Co. efforts had been made to minimise the competition between the omnibuses and the tramways, and considerable progress had been made in that direction, but a complete elimination of competition was not possible, and they could not hope to do had been made in that direction, but a complete elimination of competition was not possible, and they could not hope to do more than establish such co-ordinated working arrangements as would secure to each company its fair share of the combined revenues, and further negotiations were proceeding with a view to adjusting the divergent interests on that basis. The company and the staff contributed to a fund formed by the allied London traction undertakings for the purpose of assisting the dependents of those employés who had joined the Colours, and he asked the shareholders to sanction the contributions which the company was making to that and other war relief funds. war relief funds.

Mr. C. G. TEGETMEIER seconded the motion, which was carried.

#### South Metropolitan Electric Tramways and Lighting Co., Ltd.

Lighting Co., Ltd.

The annual meeting was held on Friday last at Electrical Federation Offices, Kingsway. Mr. C. G. Tegetmeier, who presided, said that the working account of the traction section showed a balance of £22,385, or an increase of £1,112. The traffic receipts from the tramways were adversely affected by war conditions, and in place of a very considerable increase which was indicated during the first seven months of the year there was a decrease at the end of £374. On the other hand, the net profit on the working of their motor 'buses was £1,352 more, owing to their having had the benefit of their running for the whole of the year, instead of for only five months during the previous year. The electricity supply section of the business was still more adversely affected by the war conditions than the traction section. Although there was an increase of 271 in the number of consumers connected, which was a larger increase than they had ever had previously in any one year, the revenue from the sale of current to private consumers was only £654 more than in the preceding year. That comparatively small increase was attributable solely to the restrictions upon lighting imposed by the authorities consumers was only £654 more than in the preceding year. That comparatively small increase was attributable solely to the restrictions upon lighting imposed by the authorities since the outbreak of war, and the fact that they were able to show even a small increase under the conditions that had prevailed must be regarded as satisfactory evidence of the progressive character of the business. With a return to normal conditions there could be little doubt as to its continuous and profitable development. The capital expenditure during the year amounted to £4,960, practically the whole of which was spent upon the lighting undertaking, £3,947 being expended on the extension of the mains. Expenditure of that nature became necessary as the districts comprised within their large area of supply became settled, and it was likely to be increasingly remunerative. The net profit for the year, after setting aside £3,000 to the renewals fund, the same as in the previous year, amounted to £15,966. With the amount brought forward they had £16.721 available for distribution. They proposed to place £4,500 to the reserve fund, to pay a dividend on the 6 per cent. preference shares in respect of the year 1913, and an instalment of 1 per cent. in respect of the year 1914. That would leave £351 to be carried forward. 90 per cent. of the company's staff—in fact nearly the whole of those eligible—had joined the Forces, and the whole of the present staff were contributing to the fund which had been organised by the companies with whom they were associated, for the assistance of the dependents of those of their employés who by the companies with whom they were associated, for the assistance of the dependents of those of their employes who had enlisted. The companies themselves subscribed an equal amount to that contributed by the men.

Mr. E. Garcke seconded the resolution, which was carried unanimously.

#### Guildford Electricity Supply Co., Ltd.

DURING 1914 the company made satisfactory progress, the gross receipts being £12,356, showing an increased revenue of £571. There was a balance on the revenue account of £3,947 (after crediting depreciation fund account with £1,000) as compared with £4,044 for 1913. After making provision for debenture interest, dividend on preference shares, etc., and placing £250 to the credit of reserve fund account, they had £1,149 available for distribution, out of which they recommended the payment of a dividend at the rate of 5 per cent., less tax, on the ordinary shares, absorbing £760, thereby leaving £390 to be carried forward.

Year.	Cor	nection	ns. To	tal Revenu	e. To	otal Costs	. G	ross Profit.

#### South London Electric Supply Corporation, Ltd.

The annual meeting was held on March 23rd, at the Cannon Street Hotel, E.C. Mr. J. ATHERTON, who presided, said that during the first half of the year excellent results had been obtained in respect to additional lamps connected, revenue obtained, and gross profit earned. The increase in revenue obtained, and gross profit earned. The increase in units sold was 431,567, or 161 per cent. for the half-year, and they had every reason to hope that this rate of progress would they had every reason to hope that this rate of progress would have been continued in the second half-year, but the outbreak of war had the immediate effect of reducing their output, which, however, was gradually recovering to normal in September, when in the latter part of that month the regulations in respect to the disuse of outside lighting were put into force, thus instantaneously forcing down their output for lighting purposes. They had especially felt this, as the shopping districts in their area of supply depended largely upon electricity for outside illumination. These restrictions still remained in force, but, notwithstanding, the total units sold during the year amounted to 6,153,241, and showed an increase over the previous year of 412,015, or 7.2 per cent, for the full year. The extended use of electricity for power purposes had largely contributed to this satisfactory result, for during the year 98 motors of 933 H.P. had been connected to the mains, making a total of 6,304 H.P. on consumers' premises. Further, the addinotors of 933 H.P. had been connected to the mains, making a total of 6,304 H.P. on consumers' premises. Further, the additional connections amounted to 1,355 kw., or the equivalent of 38,742 35-watt lamps, and nearly 10,000 in excess of any previous year. This constituted a record for any one year since the commencement of their operations. The gross revenue had increased by £3,385, and the working costs from £23,475 to £25,431. The profit had thus increased £1,429, which was satisfactory, as the period under review included five months of war; and notwithstanding increased costs for labour, coal, and in fact for all commodities used in their business, the total of war; and notwithstanding increased costs for labour, coal, and in fact for all commodities used in their business, the total cost per unit sold worked out at the satisfactory figure of .99d. per unit sold, as compared with .98d. in 1913. The capital expenditure during the year amounted to £11,487, of which £1,081 was for buildings, machinery and plant; £1,331 for coal elevating and mechanical stoker plant; mains £5,382, and transformers and meters £1,946, and on special items, including construction of show-rooms and for plant on hire, etc., £1,493 net, after writing off £978 for depreciation. They were satisfied that the expenditure incurred on the show-rooms including construction of show-rooms and for plant on hire, etc., £1.493 net, after writing off £978 for depreciation. They were satisfied that the expenditure incurred on the show-rooms would well repay them. After referring to the withdrawal of the London electric supply Bills, the Chairman said that at the last meeting they took powers to create £50,000 new capital, divided into 10,000 6 per cent, cumulative preference shares of £5 each, and of these 6,000 were offered for subscription to the existing shareholders and debenture stockholders of the company and were fully subscribed. In view of the momentous events which had taken place since the date of issue, he thought they might congratulate themselves upon having made the issue when they did, thus providing the company with funds so that it might actively prosecute its business. During the latter part of the year they co-opted as directors Mr. J. B. Braithwaite and Mr. H. B. Renwick, of the County of London Electric Supply Co., Ltd., that company having acquired a considerable financial interest in the company with a view to their closer relationship and for mutual assistance, their areas of supply being contiguous. They were fortunate in securing the assistance of these two gentlemen, whose presence on the board would add considerable strength to the directorate. They had had unrivalled experience in dealing with electric supply problems, particularly in connection with the development of electric supply in London, and this should prove of great benefit to the company, not only in developing their own business, but also in dealing with the

broader question of the London electric supply problem and the many troublesome and complicated points arising from it. About 25 per cent. of their normal establishment having joined the Colours, this representing nearly 50 per cent. of the eligible men in the company's employ, a point had now been reached making it inadvisable for any more employés to leave the company's service for the Colours, as the principal departments would then become under-manned, a condition of affairs which would be serious in view of the public service which was being given, and of the fact that a large number of factories in Lambeth were working directly or indirectly on Government work and depended almost wholly upon their supply for driving their machinery and lighting their premises. Much as they congratulated those men who had left to serve their King and country, it must not be forgotten that those who were compelled to remain behind on this public work and its maintenance carried serious responsibroader question of the London electric supply problem and their premises. Much as they congratulated those men who had left to serve their King and country, it must not be for gotten that those who were compelled to remain behind on this public work and its maintenance carried serious responsibility, much of which could only be entrusted to specially-trained men possessing the necessary skill and experience. They were making money allowances to all those who had enlisted, and although this would be a heavy burden, the board felt sure they would think it only right that their dependents and others should be well looked after in the breadwinner's absence; and to those men who were still in the company's service, war bonuses on a graduated scale were being given to assist them in the extra cost of living. There had been, and were still, many difficulties to contend with in the proper maintenance of their supply, and coal bulked largely. At times there had been serious difficulty in obtaining adequate supplies, principally owing to congestion on the railways due to the movement of troops and military stores, and to the great shortage of railway wagons, and to the lessened output from the collieries owing to so many of the miners having enlisted. They were having to pay considerably in excess of their contract prices for some of their coal, and although they raised their charge for supply to some of their consumers early last year, it might again be necessary to further increase the rates to compensate them for the considerably greater expenses to which they were committed under the prevailing conditions. The available balance was sufficient to pay a dividend of 5½ per cent. on the ordinary shares, as in 1913, and still leave sufficient to pay a further 1 per cent. on the ordinary share capital, but having regard to the unknown conditions through which they might have to pass during the present year, they considered that the interests of all concerned would be better served by paying a dividend of 5 per cent. for the past year, which would enable them to strengthen their c

#### British Insulated and Helsby Cables, Ltd.

DR. E. K. Muspratt presided at the annual meeting, held at Liverpool, on March 22nd. He said the profit for 1914 was £277,428, an increase of £30,077. The results were very satis-£277,428, an increase of £30,077. The results were very same factory considering that the profits were greater than the company had made in any previous year, and that for about half the year the working had been under war conditions. The half the year the working had been under war conditions. The extra profits were not due to orders for war supplies. Work had been done both for the War Office and the Admiralty, but the total was not large enough to materially affect the earnings as a whole. The war had affected business with many of the company's best customers, such as municipal corporations and large electric light and power companies, who had ordered less than they would have done in normal times. On the other hand, the company had done a much larger business than before the war with neutral countries. No consignment of manufactures on the prohibited list had been despatched to any neutral country without the knowledge and consent of the British Government or without care to prevent them reaching an alien enemy. The general result had been that the company's factories had been very busy throughout of the British Government or without care to prevent them reaching an alien enemy. The general result had been that the company's factories had been very busy throughout the whole of the year, and the unexecuted orders in hand at the present time were more than ever before. A considerable number of the company's staff had joined the forces, and both they and their dependents had been liberally dealt with by the board. The staff and workpeople had also on their part, by voluntary weekly subscription, contributed to relief funds to the extent of over £1.000. The company was now paving a war bonus to its employés to meet the enhanced cost of living. Having regard to the good results of the year's trading the directors had felt justified in setting aside £25,000 towards the formation of a pension fund, which had been under consideration for several years past. They felt they could hardly expect to retain in their service the very best men without some such provision, and they felt that the formation of such a fund was in the lest interests of the company and the shareholders, and that in making it they were following the example of the Government and many large and successful companies. folders, and that in making it they were following the example of the Government and many large and successful companies. The extinguishing of the item of patents and goodwill had much strengthened the balance sheet. Alluding to the investments of the company, the Chairman said they now stood at £531,423, as compared with £525.828 in the previous year; a valuation of the investments had been made, with the result that the figure came out at some thousands more than the

amount appearing in the balance sheet. The two companies, namely, the Midland Electric Corporation for Power Distribution, Ltd., and the Electric Supply Co. of Victoria, Ltd., in which the British Insulated held considerable interests, were making satisfactory progress, and the Automatic Telephone Mfg. Co., Ltd., in which the British Insulated also had a large appropriate the constant of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of the same of large shareholding, was now for the first time paying a divident of 3 per cent. on its ordinary shares, the profits having risen from £24,166 to £38,263, an increase of £14,097. The cash resources of the British Insulated Co. now amounted to no less a sum than £270,862, and the directors considered, especially under present war conditions, that this strengthened the position of the company very much indeed and brought many contracts which it would otherwise be impossible to deal with. One such contract at present in hand was for the Australian Conserpment, amounting to about 660,000 tralian Government, amounting to about £600,000. The report was adopted.

#### , Automatic Telephone Manufacturing: Co., Ltd.

At the third annual meeting, held in Liverpool on March 22nd, Mr. James Taylor (Chairman) said the profit for the year amounted to £38,248, an increase of £14,081, which indicated satisfactory progress. In recommending a 3 per cent. dividend they felt that in present times, if able to pay a small dividend they should do so, as investors had so many calls on their incomes, which were already in many cases reduced. There had been a substantial increase in the company's turnover during the year, and this increase was chiefly due to the over during the year, and this increase was chiefly due to the fact that a good start had been made in executing the orders for automatic exchanges referred to in his report of last year. The present position of the automatic section of the business was as follows:—The four exchanges at Epson, the General Post Office, Simla in India, and Cordoba in Argentina, continued to work well, and to the satisfaction of the purchasers. The traffic on these exchanges had increased at a greater rate than was usual with exchanges worked on the manual system, than was usual with exchanges worked on the manual system, and in consequence extensions of the plant had already been called for. The exchange at Rosario referred to last year had been completed, and was working satisfactorily. Quite recently the automatic exchange at Accrington had successfully been brought into service. The company had also in hand exchanges for Leeds, Newport, Blackburn, Chepstow, Paisley and Portsmouth, on all of which good progress had been made, and all of which the company was prepared to complete this year, but some delay might arise in bringing them into use on account of circumstances beyond the control of the company account of circumstances beyond the control of the company. From the reports of those working, both here and abroad, they felt every confidence in the future of automatic telephones. During the year the company had continued to receive assistance from the Automatic Electric Co. of Chicago, but it was acce from the Automatic Electric Co. of Chicago, but it was satisfactory to know that they were now able to manufacture in this country all except a small percentage of the equipment of an automatic exchange. The general business of the company during the year in ordinary telephone and telegraph instruments had been satisfactory, and at considerable inconvenience they had undertaken work for the Admiralty and the War Office.
The report was adopted.

#### Madras Electric Tramways (1904), Ltd.

Madras Electric Tramways (1904), Ltd.

The annual meeting was held on March 23rd at Dashwood House, E.C., Mr. A. M. Quill presiding.

In proposing the adoption of the report, the Chairman said the accounts for 1914 showed a balance from running account of £21,356 as compared with £20,975, an increase of £381, or, say, 1½ per cent. The gross receipts amounted to Rs. 6,66,633, compared with Rs. 6,44,201 in 1913. An increase of 8.7 per cent. was shown for the first seven months of 1914, but after war was declared business in Madras suffered in common with that of all other places, and during the last five months of the year the traffic receipts steadily fell. The increase for the whole year, therefore, was only 3.5 per cent. They were still suffering from the depression, the receipts this year to the middle of March being 2.2 per cent. less than the corresponding period of 1914, but perhaps they had reason to be thankful that things were no worse. The number of passengers carried in 1914 was 17,622,219, an increase of 5.22 per cent. The cost of running had shown an increase, due chiefly to repairs rendered necessary by the monsoon (which was unusually severe last year), and the net increase from running was accordingly only 1½ per cent. At the last meeting he informed them that Government had suggested a scheme of road widening in only 14 per cent. At the last meeting he informed them that Government had suggested a scheme of road widening in Chintadripet, which would have enabled another line of rails to be laid in that district. As these negotiations had been proceeding for some years the board decided that Mr. Gray proceeding for some years the board decided that Mr. Gray should visit Madras and endeavour to effect a settlement, because until a diversion of the line was made it was impossible to proceed with any extensions, or, indeed, to develop the existing lines further. As neither the Corporation of Madras nor the company could contribute towards the cost of street widening, another route had to be considered, and the diversion which they had all along advocated, viz., along Mount Road, over Government House Bridge and along Body Guard Road to the Central Station, had now been sanctioned by the Corporation. This route would necessitate the widening of

Government House Bridge and Penitentiary Bridge, and plans had been submitted for the approval of Government. He trusted that these would be passed without undue delay and so permit the development of the undertaking to proceed. A scheme for providing accommodation for the natives in the suburbs of Madras was now being considered by Government and the Corporation, and he was glad to say that the routes for extensions which they themselves had in contemplation coincided in a large measure with those recommended by the

suburbs of Madras was now being considered by Government and the Corporation, and he was glad to say that the routes for extensions which they themselves had in contemplation coincided in a large measure with those recommended by the authorities, but the distance which these extensions were to be carried would require further consideration. Meantime, they had indicated their willingness to proceed with the extensions gradually as soon as the diversion along Mount Road had been completed. The arrangements made for the joint management of the Madras Electric Supply Corporation, Ltd., and this company had proved satisfactory, and would effect savings in the management of both companies. He thought it right to mention that the company had a contingent liability in respect of a bank loan to the Madras Electric Supply Corporation, Ltd.

Mr. James Gray, in seconding the motion, referred to his recent visit to Madras, and said he fully concurred in the opinion of the company's representatives there that the diversion of the lines should be via Mount Road and Body Guard Road, as that was the direct route between the northern and the southern parts of the city. The new route would constitute, really, a trunk line, enabling them to provide a more rapid through service, and it would also permit of extensions to various parts of the city which they did not at present touch. Speaking generally, he was pleased with the condition of the undertaking. The permanent way, with the exception of two small sections, had now been laid with 90-lb rails, which were in very good condition. The buildings were of a substantial character and the workshops were equipped with all the tools necessary for building tramcar bodies and for executing repairs to the rolling stock. A petition was presented to him praying for an increase in the rates of wages and the creation of a provident fund. As a regular system of advancement was already in operation, it was not necessary to grant the former, but the creation of a contributory provident fund woul

The report was adopted.

#### A French Investment Co.

The report for 1914 of the Société Centrale pour l'Industrie Electrique, of Paris, whose board includes representatives of various large banks in Paris and leading experts in the electrical industry, records on a paid-up capital of £800,000 net profits of £43,000, which sum has been placed to a special reserve fund in consequence of the effects of the war, whilst the balance of £5,200 from 1913 has again been carried forward. It appears that the war effects were perceptible in the working of the Compagnie Centrale d'Energiè Electrique in Algiers, Oran, Rouen and Chateauroux, and a reaction is apprehended in the receipts of the Société des Tramways et Electricité, of Constantinople. The capital increase of the Compagnies Réunies Gazet Electricité, of Lisbon, was carried out, and the year 1913-14 yielded a dividend of 7½ per cent., as in 1912-13. The report refers hopefully to the capacity of development of this particular company. In addition, a further example—the Société Force Electrique, of Baku—paid for 1913 a dividend of 9 per cent. on the preference shares and 6 per cent. on the ordinary capital, and although working in 1914 was interrupted owing to a lengthy strike movement, the gross profits materially increased. It is added that despite the situation of war, the petroleum industry in the region of Baku seems to be in full activity. THE report for 1914 of the Société Centrale pour l'Industrie

#### Italian Supply Companies.

Notwithstanding the mobilisation of the Italian Armies which has been proceeding for several months past, the course of the war has not detrimentally affected any of the supply companies if we may judge from the accounts which have so far been published for 1914, although when we speak of Italian supply concerns it has to be remembered that various German and Swiss companies hold large interests in many of them, and these may be mentioned in parenthesis. The Società Adriatica di Elettricità (Zurich Bank for Electrical Enterprises), of Venice, for instance, has decided to pay 7 per cent. for 1914 on capital of £800,000, as compared with the same rate on less capital in 1913; the Società Idroelettrica Ligure, of Milan (Zurich Bank), 8 per cent. on £360,000, as against the same rate in 1913 on less capital; the Società per le Forze Idrauliche dell' Alto Po, of Milan (Zurich Bank), 8 per cent. on £184,000, as contrasted with 8 per cent; the Società Elettrica Riviera di Ponente Ing. R. Negri, of Milan (Zurich Bank and Swiss Electrical Industry Co.), 6 per cent., as in 1913, on £800,000; and the Società Lombarda per Distribuziona di Energia Elettrica, of Milan. 9 per cent. on £750,000, as compared with 10 per cent., the reduction being due to the necessity for writing down paper securities. In addition to these instances the German Schuckert group controls five subsidiary companies in Italy, four of which are NOTWITHSTANDING the mobilisation of the Italian Armies

distributing the same rates for 1914 as for the preceding year. These are the Società Sicula per Imprese Elettriche, of Palermo, 8 per cent. on capital of £320,000; the Società Toscana per Imprese Elettriche, of Florence, 10 per cent. on £400,000; the Società Bergomasca per Distribuzione di Energia Elettrica, of Bergamo, 4 per cent. on £161,000; and the Società Torinese di Tramways e Ferrovie Economiche, of Turin, 5 per cent. on £240,000. On the other hand, the fincompany—the Società Industriale Elettro-chimica di Pont St. Martin—has been compelled to refrain from paying any dividend for 1914, this result comparing with 5 per cent. on £140,000 in 1913. The explanation is to be found in the fact that the company's Bard power station was put out of service last July in consequence of damages caused by high water, and it was only possible to proceed with repair works on low-water conditions which prevailed in February of the current year. The examples given show the fair degree of prosperity which applies to a number of supply works in Italy, but they by no means exhaust the list of undertakings, including manufacturing, in which foreign capital is largely interested, and which have greatly contributed towards the industrial development of Italy.

#### British Aluminium Co., Ltd.

Mr. A. W. Tair (Chairman) presided on Friday, at Winchester House, E.C., over the annual meeting. He said that trading profit and other income for the year was £272,256, as compared with £268,720, or an increase of £3,535. These results showed some slight improvement over the previous year, which up to that time was the best result obtained since the company was originally incorporated in the year 1894. In last year's report, and in his remarks at the annual meeting, he mentioned that, although the results were good, no progress could be made in an absolutely straight line, and, in March last, in common with other industries, there was a temporary set-back in the demand. This set-back continued for several months, but about the middle of the year there was a gradual improvement in the position. The prospects were, however, considerably upset on the outbreak of the war. When this occurred, there was naturally a period of consider-When this occurred, there was naturally a period of considerable anxiety, because the company sold its production practically all over the world, and a large portion of that production had usually been sold in Germany, which had been the largest user of aluminium in Europe. The war, therefore, involved the cancellation of a considerable number of orders and contracts which worm upon the company, backet but he largest user of aluminium in Europe. The war, therefore, involved the cancellation of a considerable number of orders and contracts which were upon the company's books; but he was pleased to say that, so far as the year under review was concerned, this had been offset by the increased demand of the British Government and its Allies and contractors working for them. The result of the year had, therefore, been that the output and sales showed an increase over the previous year, and the prices realised were approximately on the same level as the previous year. The costs of production were, however, affected—specially in the closing months of the year—by the increased prices of certain materials, freight, insurance, and other expenses. He thought, therefore, considering the slackness in the demand at the beginning of the year and the abnormal conditions suddenly created by the war, the results were on the whole satisfactory. With regard to the demand for aluminium, this, in their opinion, still continued to increase, although it was a little difficult to forecast what the position would be after the war. There was, however, ample scope for development in the various uses of the metal. At the present time, there was a good demand for the metal for war material, equipment and stores; but how far this exceptional and unusual demand would be taken up by general commercial development afterwards it was somewhat difficult to forecast. There was every reason to believe, however, that as regarded the year 1915 the company would be able to market the larger part, if not the whole, of its production for the current year was dependent very largely on two factors, viz., (1) labour, (2) ability to obtain and maintain the necessary stocks of raw material and coal. Owing to the splendid response which had been made by the young men of this country to the call for service to the Empire, and owing to the Government call on the labour that remained being a paramount one, it was extremely difficult for other employers of labour to ma to the Government call on the labour that remained being a paramount one, it was extremely difficult for other employers of labour to maintain adequate forces. So far as their company was concerned, the response to the country's call had been extraordinarily good. The number of members of the stuff and employés who had joined the Colours was about 550, which was approximately 22 per cent. of their total forces. Two of their directors were serving also, namely. Captain Pollen and Captain Cooper. In accordance with the general custom which had been adopted by the various manufacturers in this country, they had made provision for the dependents of the members of their staff and the families of their employés who had joined the forces. Their industry, which was very largely a specialised one, required a considerable period ployés who had joined the forces. Their industry, which was very largely a specialised one, required a considerable period of training on the part of the men before they were able to give efficient labour, and, for some time past, it had been increasingly difficult to supply the gradual wastage which had occurred due to causes which he had mentioned. They were employing a certain number of Belgians, but the supply of those who were capable and willing to work was very far below the demand of the labour market at the present time. Their staff and men, however, had been working in an excel-

lent way, and had responded exceedingly well to the additional strain put upon them, and they hoped that they might be able to keep the whole of their works going during the year nearly up to their full capacity. With regard to the second difficulty, namely, that of obtaining and maintaining the necessary supplies of raw material and coal at the various works, their chief difficulty was with regard to their principal raw material—bauxite. This was obtained from their mines and from stocks in the South of France. Immediately after the outbreak of war, the French Government declared bauxite contraband and placed an absolute bar upon its exportation. They were able, however, with the help of the Foreign Office, to convince the French Government of the absolute necessity for this raw material to enable the company to supply Government contracts, and a special permit was given for export, although it was still necessary to obtain a special permit for each cargo, which very often involved delay and demurrage. Apart from that, it was becoming increasingly difficult to obtain the necessary freighting facilities to their works. In order that the characteristic terms of the characteristic terms of the characteristic terms of the characteristic terms of the characteristic terms of the characteristic terms of the characteristic terms of the characteristic terms of the characteristic terms of the characteristic terms of the characteristic terms of the characteristic terms of the characteristic terms of the characteristic terms of the characteristic terms of the characteristic terms of the characteristic terms of the characteristic terms of the characteristic terms of the characteristic terms of the characteristic terms of the characteristic terms of the characteristic terms of the characteristic terms of the characteristic terms of the characteristic terms of the characteristic terms of the characteristic terms of the characteristic terms of the characteristic terms of the characteristic terms of the characteristic terms of the characteristic terms of the characteristic terms of the characteristic terms of the characteristic terms of the characteristic terms of the characteristic terms of the characteristic terms of the characteristic terms of the characteristic terms of the characteristic terms of the characteristic terms of the characteristic terms of the characteristic terms of the characteristic terms of the characteristic terms of the characteristic terms of the characteristic terms of the characteristic terms of the characteristic terms of the characteristic terms of the characteristic terms of the characteristic terms of the characteristic terms of the characteristic terms of the characteristic terms of the characteristic terms of the characteristic terms of the characteristic te although it was still necessary to obtain a special permit for each cargo, which very often involved delay and demurrage. Apart from that, it was becoming increasingly difficult to obtain the necessary freighting facilities to their works. In order that the shareholders might appreciate to what extent this disturbance and increase in prices affected the company's costs of production, he might mention that, in the course of a year, they had to deal with approximately 200,000 tons of seaborne freight. The market for coal had also been affected, and there was also a heavy burden in connection with insurance to cover marine and war risks on raw materials and metal. It was not possible in any considerable measure to raise the price of the metal to compensate for these increases in expenditure, as a large quantity was contracted for before these troubles became manifest, and it had also been the desire to prevent any great fluctuation in prices in order to protect and encourage the users of the metal. In a business of this magnitude, a certain amount of capital expenditure must always be going on. The preliminary work for the rection of the new alumina works at Burntisland was in progress, but, owing to difficulties in obtaining labour and material, it was not expected that these works could be in operation until next year. The power plant required for the rolling mills at Warrington had been completed, and these mills were now operating satisfactorily to their full capacity. The final balance of the purchase price for the acquisition of the works at Vigelands, Norway, from the Anglo-Norwegian Aluminium Co., was completed in June last. This purchase was an advantageous one for the company, and had largely increased their productive capacity. The acquisition of those works necessitated the increases in their carbon-electrode works at Kinlochleven and the erection of the own had been completed in the course of next year, and, as all the capital necessary working capital for their operation, had been found out of the re was largely to be accounted for by the increase in the working stocks at their various factories. Sundry debtors and bills receivable stood at £119.561, as compared with £91,400, or an increase of approximately £28,000. This amount was after making provision for all bad and doubtful debts, and in this connection he might mention that all debts due by parties in Germany, which he was pleased to say were not of very large amount at the outbreak of the war, had been written down to a nominal sum. Cash in hand and at bankers stood at £163.308, as compared with £140,092, or an increase of approximately £23,200 over the previous year. It was necessary for a company of their magnitude to keep a large cash reserve, and more particularly so in the present times. The allocations to reserve account for the last two years, amounting to £100,000, had not been invested in securities outside the company's business owing to the necessity of making provision #100.000, had not been invested in securities outside the company's business owing to the necessity of making provision for capital expenditure. The dividend recommended by the board on the ordinary share capital was at the same rate as the previous year, and, in view of the difficulties which he had mentioned, the board considered it was prudent that the dividend on the ordinary shares of the company should not be increased. They felt that in these company has produced and the company and the company and the company and the company and the company and the company and the company and the company and the company and the company and the company and the company and the company and the company and the company and the company and the company and the company and the company and the company and the company and the company and the company and the company and the company and the company and the company and the company and the company and the company and the company and the company and the company and the company and the company and the company and the company and the company and the company and the company and the company and the company and the company and the company and the company and the company and the company and the company and the company and the company and the company and the company and the company and the company and the company and the company and the company and the company and the company and the company and the company and the company and the company and the company and the company and the company and the company and the company and the company and the company and the company and the company and the company and the company and the company and the company and the company and the company and the company and the company and the company and the company and the company and the company and the company and the company and the company and the company and the company and the company and the company and the company and the company and the company and the company and the company and the company and the company and increased. They felt that in these somewhat uncertain and difficult times the interests of the shareholders would be best served by maintaining the dividend on the ordinary share capital for the year 1914 at the same rate as the previous year. It was evident from Press cuttings that there had been an idea in the minds of several persons that the company had benefited largely by the war, but this was not the case. In the minds of others, there seemed to be an extraordinary

ignorance of the company's manufactures, because in one paper it was quoted with all seriousness that the company was doing it was quoted with all seriousness that the company was doing extraordinarily well, working night and day for the Government in the manufacture of aeroplane engines. The company were producers of aluminium in crude and manufactured form, but they did not undertake complicated questions of mechanical engineering such as those which had been attributed to them.

Mr. J. Taylor seconded the motion.

Mr. C. Hacking asked what were the prospects of the company recovering its trade with Germany after the war?

The CHAIRMAN said that Germany had been the largest users of aluminium in Europe, and it was difficult to forecast what would happen. Germany manufactured a very small amount of aluminium and must come into the markets of the world to purchase. He did not anticipate that there would be the slightest difficulty in doing trade with Germany if they desired to do it.

to do it.

The motion was carried, as was also a resolution of thanks

to the board and staff.

## Marconi's Wireless Telegraph Co., Ltd.

Marconi's Wireless Telegraph Co., Ltd.

The directors have declared a dividend of 7 per cent., less income tax, upon the 250,000 7 per cent. cum, participating pref. shares in respect of the year 1914, payable on April 19th. In making this announcement the directors say that the company has continued since the outbreak of war in full centrol of its business, but its stations have been largely devoted to Government work. For this reason the new direct public service with New York, which it had been contemplated would have been opened in the summer of last year, has had to be postponed. In other respects the company's business has been necessarily disturbed, and considerable business which was pending in many foreign countries has been delayed or deferred. This, however, has been substantially compensated for by Government and other business directly resulting from the war; the works and all the company's staff have been working under the highest pressure the oughout the whole period. A number of matters, including the question of compensation and payment for services, being still in abeyance, the directors are as yet unable to estimate with sufficient reliability the results of the business of last year to warrant them at this moment in declaring an interim dividend upon the ordinary shares. They are however, of oninion that there reliability the results of the business of last year to warrant them at this moment in declaring an interim dividend upon the ordinary shares. They are, however, of opinion that there is no reason for deferring the dividend upon the preference shares. The directors say that they contemplated being in a position to give shareholders information with regard to other matters of importance concerning the company's business, but as these still remain under negotiation, it has been resolved not to delay further this announcement and the payment of the dividend.

#### STOCKS AND SHARES.

TUESDAY EVENING.

At this season of the year, the coming of the Easter Holidays always necessitates earlier preparation of matter, as well as advertisements, for the Electrical Review, and this is the reason why the financial section has to be made up earlier than usual. The approach of Easter in the ordinary way is a signal for Stock Exchange business to slack off, but in this year of surprises it is not so astonishing to find that the House is developing a good deal of activity. Possibly this may be because most people are compelled, for one reason or another, to curtail their Easter holidays. Some are too busy to go away; others are too idle. The position may be illustrated by the traditional Stock Exchange complaint that when members are making a lot of money, they have no time to spend it; and when they have plenty of time to spend money, it means that they are not making any. The withdrawal of the usual railway facilities, which presses so hardly upon thousands of the workers in the Metropolis, offers another excuse for staying in town by those to whom a holiday flight to golfing grounds or the seaside has been in previous years a matter of course.

As was foreshadowed here last week, the price of electricity is to be put up; and this will come as no surprise to those who have any acquaintance with the conditions under which concerns connected with the industry, or with gas, are labouring at the present time. When gas companies raise the price of their product they are obliged to lower their dividends. Electric lighting companies, however, are not confined by any such sliding scale as that which operates in the case of the gas At this season of the year, the coming of the Easter Holi-

their product they are obliged to lower their dividends. Electric lighting companies, however, are not confined by any such sliding scale as that which operates in the case of the gas companies; but it would be too much to expect that the former will maintain their dividends if the raising of the price of current has any pronounced effect upon consumption. These are, however, too early days to discuss the matter with any degree of certainty; and it is mentioned merely as a hint to shareholders that they may be called upon to make some further sacrifice, in addition to whatever disabilities they have already suffered in consequence of the war.

The leading article in last week's issue dealt with the serious aspect presented to many electricity undertakers through the

aspect presented to many electricity undertakers through the Treasury limitations of capital expenditure. The subject is

one closely concerning the companies; as well as local authorities, and it has been already discussed earnestly in certain board-rooms. Fortunately, the charge of extravagance in capital expenditure is one that has been rarely levelled at elec-

ties, and it has been already discussed earnestly in certain board-rooms. Fortunately, the charge of extravagance in capital expenditure is one that has been rarely levelled at electricity supply companies—at any rate, within the past half-decade; and this has been due largely to the fact that the continual discussion of schemes for taking over the companies, with a view to the constitution of one central authority for the supply of London as a whole, has been ever-present to the minds of those charged with the control of the business.

So it comes about that the spending departments have lived in an atmosphere of wholesome economy; and that further capital expenditure may be prohibited by the Treasury is a threat which will probably convey less terror to directors in the electrical world than to most other branches of domestic industry. Still, those companies which are well buttressed with reserves have additional cause for congratulation at this time. It is understood in the Stock Exchange—to whose Committee are forwarded copies of applications made by companies for new capital issues—that the Treasury interprets its prohibitory powers with a reasonable amount of elasticity, and that, where definite cause of national interest can be shown, the applicant for permission to raise more money can reckon upon his proposals meeting with at least favourable consideration.

This week a large number of ex-dividend markings have been made, and already in some cases deductions have been recovered, either wholly or in part. County ordinary, for instance, at 11½ have regained the full amount of the dividend. South Londons are up to 3 xd. The fall in Westminsters has been checked, the price recovering ½ to 7½. Cities at 14½ are ex their dividend, and in several of the leading shares this re-arrangement of prices has resulted in investment purchases.

The rumour linking the South London and the South Metropolitan Companies with the County of London Electric Supply Co. has gained ground since we referred to it—with intentiona

Marconi shares have gone back a little to 35s, sellers—not because the company has just lost an action for damages in which a comparatively small sum was involved, but because the directors announce that they cannot declare an interim dividend upon the ordinary shares at the moment. A number of matters, they say, including the question of compensation and payment for services being still in abeyance, they are as yet unable to estimate with sufficient reliability the results of the business of last year, but they are of opinion that there is no reason for deferring the dividend upon the preference shares. Matters of importance concerning the company's business are still under negotiation but the director state that

shares. Matters of importance concerning the company's business are still under negotiation, but the directors state that some of the disturbance caused by the war has been sufficiently compensated; and they add that the works and all the company's staff have been working under the highest pressure throughout the whole period covered by the war. The preference are steady at 33s., and, in the subsidiaries, small falls lowered American Marconis to 9s. 3d., and Canadians to 5s. 3d. The outstanding feature in the telegraph market is the strength of Easterns, the stock having risen 2½ to 131½, thus passing its end-July, 1914, level. "China" shares now stand the same as they did at that time, and Easterns at 13½ are but 7s. 6d. lower. The market shows decided strength, but, oddly enough, a few of the prior-charge stocks are on offer, for which the reason probably must be sought in the fact that new gilt-edged issues are being made at prices so tempting that they encourage holders of existing stocks to sell these, and to encourage holders of existing stocks to sell these, and to

mapply for the newcomers.

Mexico Trams are 5 points lower. Brazil Tractions, on a decline in the Rio rate of exchange to 13 7/32d., continued to droop. The Anglo-Argentine Tramways division is fairly steady, and likely to improve, since the suspicion with which most Argentine things have been regarded is now wearing off and the reitween market conscious whilsten now wearing of and the reitween market conscious whilsten now wearing of and the railway market especially exhibits new signs of

Callenders, Henleys, and India-Rubber shares are all better. British Insulateds have hardened to 11, ex the dividend of 11s. Electric Constructions rose a few pence. Telegraph Constructions are 10s. easier, heavy shares such as these being vulnerable to the offering of any small amount. Edison and Swan have eased of a little, and the first debenture is 2 points lower at 63. British Swan have eased off a little, and the first debenture is 2 points lower at 63. Armament shares rallied a little, and the rubber market is one of the best in the Stock Exchange. Renewed attention has been called to the excellent position of most of the well-managed concerns; and since proprietors are in no mood for selling, the demand which has sprung up from investors has had a bracing effect upon the market, although at the same time it has been difficult to satisfy the same time it has been difficult to satisfy.

Midland Electric Corporation for Power Distribution, Ltd.—The report states that the revenue was adversely affected during the first two months of the war, but, apart from the supply of energy for light, has since improved. The balance to the credit of the net revenue account, after payment of debenture interest, is £17.859, plus £3.572 brought forward, making £21,481, of which the directors have appropriated to depreciation of plant and machinery, £8.582; depreciation of stores, £500; writing off of commission and expenses of issues of debentures and shares and expenses during construction. £4.275; payment of a shares, and expenses during construction, £4.275; payment of a dividend of 6 per cent. on 13,079 preference shares, £3,923; transfer to a debenture premium redemption account, £500; carrying forward £3,650.—Financier.

Lancashire Dynamo and Motor Co., Ltd.—The Times states that the ordinary share dividend is 8 per cent. for the year, free of tax.

#### MARKET QUOTATIONS.

P. R. Jackson & Co., Ltd.—The Financial Times states that for 1914 the gross profit was £18,475, and after payment of interest on debentures, depreciation, &c., there is a balance of £8 948. The directors recommend a dividend of 6 per cent. on the ordinary shares, writing off goodwill account £2,000 and leaving to be carried forward £1,756.

Winnipeg Electric Railway Co.—For 1914 the net earnings amounted to \$1,885,093, and after providing for fixed charges and four quarterly dividends of 3 per cent. each, a credit to profit and loss of \$901,697 brought forward was reduced to \$816,309. A dividend of 2½ per cent. has been declared for the quarter ending March 31st.—Financial Times.

Huelva Gas and Electricity Co., Ltd.-The net report for 1914 was £2,051, plus £245 brought forward. Deducting the dividend on the preference shares, the directors recommend that £1,400 be written off for depreciation of gas and electric plant, leaving £574 to be carried forward.

#### ELECTRICITY IN MINES.

THE REPORT OF H.M. ELECTRICAL INSPECTOR of Mines.]

THE report for the year 1913 of Mr. Nelson, H.M. Electrical Inspector of Mines, is included in the General Report of the Chief Inspector of Mines, which has just recently been issued.

The report deals first with the growth of the use of electricity in mines, the following being a summary of the returns received on January 21st, 1913:

•	Surface H.P.	Underground H.P.	Total H.P.
Scotland	26 279	93,361	119,640
Northern	64 837	79,422	144,259
York, and North Midland	55,954	51,245	104,200
Lancashire, North Wales	•	•	•
and Ireland	9,884	20,863	30,747
South Wales `	90,581	91,237	181,818
Midland and Southern	9,141	35,294	44,434
Totals	256,676	371,422	628,098
Total for year 1912	194,088}	316,667}	510,756

These figures show an increase of 32.24 per cent. in the electrical H.P. installed for the surface; 17:29 for underground; and a net total increase of 22.97, which is very satisfactory indeed on a year's working.

A further estimate of the growth of the use of electricity in the different divisions may be made by comparing the number of tons of mineral raised per electrical horse-power employed with the corresponding figure for the year 1912, as shown in the following table:

:	Division.		Tons of mineral raised in 1913.	Oa surface.	electrica be Below	I mineral p d H.P. emp Above and low ground together 1913.	loyed. I Carres-
Scotland		•••	47.434,287	1,805	508	395	449

United	Kingdor	n	301.611.353	1.175	812	480	534

In regard to coal-cutting, the number of electricallydriven machines in 1913 was 1,307, being an increase of 173 over the number in use at the end of 1912.

#### FATAL ACCIDENTS.

There were during the year 1913 15 fatal accidents definitely due to electricity, and causing in all 16 deaths. In addition, a serious fire at the Rig Pit of the Blaenavon Iron and Steel Co., at Blaenavon, Monmouth, on April 7th, which resulted ultimately in the loss of three lives, was held by most investigators to have been due to the failure of an electric cable, and the disaster at Senghenydd Colliery on October 14th was held by the Commissioner appointed to investigate the cause to have been possibly, but not certainly, due to sparks from electric signalling wires. two latter accidents apart, the figures for the year 1912. comparable with those given above for 1913, were 12 accidents causing 14 deaths. In 1913 there was therefore an increase of three accidents and two deaths over the figures for 1912.

The whole of the 15 accidents which occurred in were electric-shock accidents. Of these, three took place on the surface and 12 below ground. The two classes of accident will be separately considered, so that any conclusions it may be possible to draw shall have application to surface conditions and to underground conditions respectively. The figure for electric-shock accidents below ground, which had begun to show a downward tendency,

has risen again, as will be seen below :-

1907 1908 1909 1910 1911 1912 1913

Number of persons killed by electric shock below ground in coal mines ... 10 12 13 15

The figure for 1913 is disappointing in comparison with 1912, although the horse-power of electric plant in use below ground increased by 17 per cent. during the year.

For the first time it is possible, from the data available, to determine the rate of increase of the horse-power of electric plant in use below ground. On the assumption that that rate of increase is normal, and not exceptional (and there is no reason to think that it is other than normal), the horsepower of electric plant in use below ground has increased by 95 per cent. since the end of the year 1909, whereas the number of persons killed by electric shock, as will be seen, was the same in 1909 as in 1913. It is also of interest to note that of the 79 persons killed by electric shock below ground, in seven years between January 1st, 1907, and January 1st, 1914, 45 were killed in the first half of that period, and 34 in the second half; figures which, taken in conjunction with the increase of electrical horse-power in the second half period over the first half period, seem to show that the risk of fatal electric shock below ground is decidedly a diminishing risk. It is, on the other hand, unsatisfactory to note that of the 12 fatal electric-shock accidents that occurred below ground in 1913 (one of the accidents was responsible for the deaths of two persons), at least nine might have been avoided by greater care in the maintenance of apparatus and stricter regard to the regulations.

Surface Accidents.—Of the three electric-shock accidents, one occurred on a high-pressure alternating-current system, one on a medium-pressure alternating-current system, and one on a low-pressure alternating-current system. In the case first mentioned the victim of the accident touched some part of the winding of a three-phase motor supplied with current at 3,000 volts. Though the insulation appeared externally to be perfect, it was, in fact, insufficient, and a fatal electric shock followed. The accident on a mediumpressure system was of an unusual character. A derrickpole was being erected by means of steel wire guy ropes. when one of the latter made contact with an unprotected fuse in the neighbourhood belonging to a 5-H.P. motor supplied with three-phase current at 400 volts. The ground was wet, and the man who had hold of the guy rope that made contact with the fuse was killed. The fuse which caused the accident should clearly have been protected. The accident on the low-pressure system was the result of an act by the victim himself (a boy of 13), and his death may fairly be classed as a misadventure. The evidence given at the inquest showed that the boy who was killed challenged one of his mates to climb a railing, and from this position to touch some electric wires which would then be within his reach. His mate refused, so the victim himself climbed the railing and touched the wires. He was killed instantly, though the pressure was not high (220 volts alternating).

Underground Accidents. - Out of the 12 underground electric shock accidents, nine occurred on medium-pressure three-phase alternating-current systems, two on mediumpressure continuous-current systems, and one on a low-The cirpressure two-phase alternating-current system. cumstances of each of these accidents have been considered, with the result given by the following table :-

with the recard given by the remaining their	•	
Due to : —	Accident	s. Deaths
1. Faults as regards the earthing of metallic outer coverings of apparatus:—	3	
(a) Total absence of any connection to earth	1	1

The above table may be summarised thus		
		s. Deaths.
1. Contact with outer coverings of apparatus live through the absence of, or an		
inefficient, earth connection	. 6	7
2. Defective insulation of cable systems	. 4	4
3. Contact with uninsulated live parts	. 2	2
	12	13

For the period between January 1st, 1905, and December 31st, 1913, that is to say, in nine years, electric shock below ground has been responsible for 83 recorded accidents and 86 deaths. Mr. Nelson has carefully considered the available information in regard to all of these accidents (a large portion were personally investigated by him), and they may, he thinks, justly be analysed as follows:—

1. Contact with outer coverings of appara- live through the absence of an effici	atus	ccide nts	s. Death
earth connection	•••	37	40
2. Defective insulation of cable systems	•••	32	32
3. Contact with insulated live parts	•••	12	12
4. Other causes (misadventure)	•••	2	2
		83	86

Defective earthing has, therefore, been responsible for very nearly 50 per cent. of the deaths due to electric shock below ground. Imperfect insulation of cables has been responsible for 37 per cent, of such deaths.

SUMMARY OF FATAL ELECTRIC SHOCK ACCIDENTS IN 1913. Surface Accidents:—

	_				15	16

Of the accidents on the three-phase systems, 13 in all, 10 were on completely insulated systems and 3 on systems with the neutral point connected to earth.

Of the 16 persons killed by electric shock in 1913, 3 were coal-cutter attendants, 2 were surface labourers, 2 were underground road repairers, 2 were motor attendants, 1 was a haulage hand, 1 a pony driver, 1 a foreman, 1 a coal conveyor attendant, 1 a drawer, 1 a surface screen boy, and 1 a trained electrician.

### Non-Fatal Accidents.

During the year 1913, 53 separate non-fatal accidents, or dangerous occurrences, were reported. There were no non-fatal ignitions of firedamp reported as having been due to electricity, as against 1 in 1912. There were, however, 3 underground fires as against 2, and 50 electric shock accidents causing injury to 51 persons, against 36 accidents causing injury to 36 persons in 1912. All the electric-shock accidents were in mines under the Coal Mines Act, as also were all the underground fires.

Underground Fires Caused by Electricity.—Three underground fires were reported as having been due definitely to electricity in 1913.

The first occurred on January 16th at Leven Colliery, Fife, Scotland. It was caused by the breakdown of two cables which were carried through the woodwork of a trapdoor, and in contact therewith without effective insulation, and without armouring. The fire burnt for about an hour, and the woodwork of the door and some props were destroyed. No one was injured.

The second fire occurred in a haulage motor house at the Duffryn Rhondda Colliery, Port Talbot, South Wales, on March 11th. In order to shield the motor-man from the cold intake-air, a piece of brattice cloth was hung behind him, and in the neighbourhood of the cables running from the motor-controller to the resistances. The fire was caused by a short circuit in the base of the controller, which set fire to the cables referred to. The fire travelled via their outer coverings to the brattice cloth, which, in turn, caught fire, and some of the neighbouring props were scorched, but help was close at hand and the fire was quickly extinguished.

The last was the least serious of the three. It occurred in a pump room at Markham Colliery, Hollybush, near Newport, Mon., on May 2nd. A short-circuit due to a

breakdown of insulation at a cable dividing box caused an arc, which ignited the rubber insulation of some neighbouring cables. The fire spread to a rubber mat on the floor of the pump room, but it was readily extinguished by the application of a little sand.

Electric Shock Accidents.—Of the 50 electric shock accidents causing injury to 51 persons which were reported during 1913, 30, causing injury to 30 persons, took place below ground, and 20, causing injury to 21 persons, took place at the surface. Of the 51 persons injured, 43 were disabled for more than seven days. In three cases the victim was unconscious for some time, artificial respiration being successfully applied in each case. In four other cases the victims were very seriously injured by burns.

the victims were very seriously injured by burns.

The first of these four cases occurred in the generating station at the surface of Silverwood Colliery, Rotherham, Yorkshire, on February 9th. Two men were working behind a live 500-volt alternating-current switchboard, when one of them dropped a spanner across some live parts. The short-circuit caused an arc, which badly burned both men about the head and face. It is said that the men were working with current on, in disobedience to instructions.

The second of the accidents above referred to occurred in the generating station at Littleburn Colliery, Durham, on May 29th. The victim, a contractor's foreman, was explaining to a member of his firm how he intended to fix some conductors which were about to be erected behind the switchboard. He had a pair of pliers in his hand, and with these he made accidental contact with some live metal. The shock caused him to fall against three bare conductors carrying 2,750-volt alternating current. He was very seriously burnt, losing his left arm. After the accident the bare conductors were effectively protected.

The third accident occurred at Greenrigg Colliery, Fauldhouse, Linlithgow, Scotland, on August 19th, and resulted in severe burns to the victim's left arm and hand due to the failure of the insulation of a trailing cable which he was handling. The system in this case was continuous current and the pressure 500 volts.

The fourth accident occurred at Bargoed Colliery, Monmouthshire, on December 29th. In this case the victim was a switchboard attendant, and he committed the error of attempting to examine a switch which was live at the time, and which he knew to be live. He short-circuited the conductors in the neighbourhood of the switch, which was carrying 3,300-volt alternating current, and was badly burnt on the left hand, face, and neck as a result.

Unclassified Non-Fatal Accidents.—An accident of an unusual character occurred at the Prince of Wales (Haigh Moor) Colliery, near Pontefract, Yorkshire, on Angust 25th. The glass forming the peephole on a coal-cutter frame was blown out with such force that it caused incised wounds in the back of the attendant, who was at the time 10 yards from his machine. As the result of investigation and experiment it was agreed that there had been an explosion in the coal-cutter frame caused by the volatilisation of some insulating varnish, unduly heated by a short circuit in the motor armature. This short circuit also ignited the gas which formed inside the frame of the coal-cutter, and which proved to be explosive.

The chief point to be noticed in the report is the importance of having an efficient earth, and as we have on several occasions pointed out, shortcoming in this respect, in our opinion, is due not so much to neglect on the part of the management as to incompetence of the electricians in charge. It is sometimes difficult to get a really efficient "earth" in a mine, and unless the electrician in charge has a little more knowledge than a merely practical one, it is very possible he does not clearly understand how to obtain, much less maintain, an "efficient earth" as defined in the Special Rules regulating the use of electricity in mines.

It is also a little disconcerting to have three fires reported due to electricity, and shows how much care is necessary in installing and maintaining electrical cable and plant in mines. If the colliery company cannot afford the services of a really competent engineer, then at least it would pay them to have a monthly or quarterly report made by an outside engineer. Accidents are expensive, and prevention is much better than cure.

#### REVIEWS.

Samuel F. B. Morse: His Letters and Journals. Two volumes. By E. L. Morse. London: Constable and Co. Price 31s. 6d. net.

In these two volumes, which are written by his son for the purpose of giving to the world "through characteristic letters and contemporary opinions an accurate portrait of the man and a succinct history of his life and labours," we have the story of Morse the artist and inventor. With the "artist" part of the biography we do not propose to concern ourselves here, interesting though it be, and teeming with material that enables us to appreciate the man from many different aspects. Here we shall confine ourselves to the period beginning with the dinner-table conversation on board the s.s. Sully in 1832, and terminating with Morse's death 40 years later—a period of stress and trial, of buoyant hopes and crushing disappointments, ending at last in success and world-wide celebrity.

During the dinner-table conversation just alluded to the subject of electromagnetism was discussed, and Morse rose from the table with the idea that there was "no reason why intelligence might not be transmitted instantaneously by electricity," quite ignorant of the fact that the same thought had occurred to the minds of others long before his day.

That Morse first conceived the idea, or was the inventor, of the telegraph, no one to-day who knows anything of the subject would seriously maintain. The distinction of having first published the idea of applying electricity to the telegraph belongs to the historic Scotsman, "C. M.," who enunciated his views in the Scot's Magazine in 1753, and the invention attained its practical realisation in the hands of Le Sage, of Geneva, in 1774. Hence the need for the reader to guard himself against the acceptance of such expressions as "the inventor of the telegraph," which are sprinkled freely throughout the book in reference to Morse.

In our desire to do justice to Morse we must not allow ourselves to forget the work of those who had laboured at the problem before him, as well as those who were contemporary with him.

Forty-two years after the invention of Le Sage, and 16 years before Morse embarked on the Sully, our own countryman, Ronalds, of Hammersmith, had telegraphed over eight miles of wire, with such success that he presumed to suggest its adoption by the British Admiralty for coast communication purposes, only to meet with a refusal on the ground that the existing system of telegraphing (semaphore) was sufficient for their purpose.

In 1820 Ampère constructed a telegraph, using a magnetic needle, wires and a battery; in 1828 Dyer erected a telegraph line on poles, with glass insulators, on Long Island, New York, and produced signals on prepared paper by means of electricity, and in 1830, in Dublin, Booth showed how electromagnetism could be used to telegraph to a distance and cause marks to be made by the fall of the armature of a magnet when the current was Now these were all antecedent to the year 1832, broken. when Morse claimed to have had his inspiration. Thev not only embodied the idea of a telegraph, but actually were practical methods of telegraphing, although crude ones. Morse's ignorance of what had already been done—an ignorance admitted by his biographer-need hardly be wondered at when we find two Judges, who tried one of the cases in which he was involved, giving it as their opinion that "Mr. Morse was the first to devise and practise the art of recording language at telegraphic distances by the dynamic force of the electromagnet, or, indeed, by any agency whatever" (the italics are ours).

That Morse did not continue in this state of ignorance is shown by the following significant interrogatories and answers, which appear in the records of a litigation with Bain, the inventor of the electrochemical recorder:—

"Nineteenth interrogatory. Do you mean to say that you were the first to discover that when an electromagnet is connected with, and forms a part of, such circuit the magnet becomes attractive and non-attractive, as the current flows or ceases to flow? Answer: I do not.

"Twentieth. Do you mean to say that you were the first

inventor of the combining an electromagnet and an armature in a circuit of electric or galvanic conductors? Answer: No, not generally in the abstract; but I do claim to be the first inventor of combining an electromagnet and an armature, as described in my letters patent, and of combining this combination with a circuit of electric or galvanic conductors."

So much for Morse being the inventor of the telegraph. Let us now see if he can lay claim to having invented the first practical telegraph. In the year 1837 his apparatus, on his own admission, was in such an unfinished state that he was nawilling for it to be seen. In the same year Cooke and Wheatstone, in England, patented the first practical (needle) telegraph—practical in the sense of being a commercial undertaking. On June 10th, 1840, the first American patent for an electric telegraph was granted to these two inventors, and ten days later, on the 20th of the same month, Morse was granted his first patent for "a new and useful improvement in the mode of communicating information by signals by the application of electromagnetism."

These facts speak for themselves, and need no comment. Again, in order to show that Morse was not ignorant of electrical principles when he conceived the idea of a telegraph, it is contended by his biographer that he (Morse) was familiar with much that had been discovered with regard to that mysterious force (electricity) through his studies under Profs. Day and Silliman, of Yale, and through the lectures and conversations of Profs. Dana and Renwick in New York, so that the charge which was brought against him that he knew absolutely nothing of the subject, can be dismissed as proving the ignorance of his critics" (vol. 2, page 3). In a deposition made in March, 1850, Prof. Henry (the man after whom we name our practical unit of inductance) said of Morse:—"He appeared to be an unassuming and prepossessing gentleman with very little knowledge of the general principles of electricity, magnetism, or electromagnetism, &c."; and again, in giving evidence in the Bain case already referred to, the same high authority stated :- "I am not aware that Mr. Morse has ever made a single original discovery in electricity, magnetism, or electromagnetism applicable to the invention of the telegraph. have considered his merit to consist in combining and applying the discoveries of others in the invention of a particular instrument and process for telegraphic purposes."

When reading through these pages, if we are to prevent our judgment from becoming obscured by the admiration which this fine tribute of a son to the memory of his father evokes within us, we must bear the facts in mind; for there is much, apart from the vexed question of priority, that we should like to dwell upon in this story of a man who voluntarily relinquished a remunerative profession, in which he had attained to a place of high distinction, to tread the rough and thorny path of the inventor, wherein he was to suffer penury and want, obloquy and insult, and be looked upon as an eccentric and a visionary.

We do not admit his claims, which in this book are reaffirmed, because in the truer perspective, with which the lapse of years has furnished us, we are enabled to estimate his position and work more dispassionately and impartially than was possible for his contemporaries; but in doing so, we recognise his right to a conspicuous place amongst the many workers who have contributed to the progress of electromagnetic telegraphy.

Much has been achieved since the days of Morse; and the advent of fast-speed printing telegraphs and multiplex telegraphs is threatening to displace whatever remains of the more modern form of his recorder in the shape of the Wheatstone receiver. But when we contemplate the long evolutionary process which has resulted in the marvellous systems at our disposal to-day, and try to single out any one name as that of the "inventor of the telegraph," we the more consciously recognise the truth of Sabine's remark that the arrogance of any individual claim to the title cannot be recognised; and those men who deserve the most credit happen to be those who advance the least claim to it."

^{* &}quot;Telegraph History and Progress," by Robert Sabine, C.E.

Dynamo and Electric Motor Building. By A. H. AVERY.

London: Cassell & Co., Ltd. Price 1s. net.

In this volume the author has done justice to his long experience in the art of building small dynamo-electric machines, by providing at a purely nominal price a fully illustrated and thoroughly practical treatment of the alternative constructions available, and the materials and methods of construction and assembly best suited to the needs of the amateur with limited resources. Chapter I presents a simple and clear explanation of the fundamental principles of dynamo-electric current generation, and is followed by an equally clear explanation of the function of the commutator, the effect of brush width, angular lead, and auxiliary poles. The author is to be complimented on dealing with these topics without introducing theoretical matter so tempting to the expert and so confusing to the amateur; the explanations given are clear, simple, and quite concordant with the practical nature of the work.

The general requirements and materials of field magnets are outlined in Chapter III, and the relative merits of different types of field systems are discussed briefly. desirability of laminating armature cores is explained in the next chapter and the practical merits of different forms of stampings are discussed; means for ventilating the core might be described a little more fully and the use of wedging strips instead of binding wires deserves mention. In dealing with commutator construction the author becomes rather general in his remarks; more definite and practical information is here required by amateurs. Brushes and brush gear are dealt with in considerable detail; the relative merits of various brush materials and the reasons for and applicability of different mounting methods are discussed, but here again a little more definite practical information might be included. Next follow three chapters on insulation and windings to which the author rightly attaches great importance, for defects in the material or arrangement of field and armature windings are responsible for most troubles in home-built machines. The instructions and illustrations here presented are admirable and should meet all requirements.

Both hand and former wound armature coils are considered. Chapter IX presents full working instructions for the building of a 120-watt motor-dynamo converter, it being assumed that the reader buys the main castings ready made. The principle of working of the converter is first explained, then follow detailed and fully-illustrated instructions as to the sequence and manner in which machining and erecting are to be performed. This chapter is beyond criticism, and the notes concerning commutator and brush gear construction rectify the slight deficiencies noted in the chapters relating specifically to these topics. Chapter X includes general notes, and outline working instructions for the building of a number of small dynamos and motors, besides giving more detailed treatment of the construction of a 1-H.P. motor. The working drawings are clear and to scale, and include only essential dimensions. Suitable winding quantities and speeds are merely stated, and one wonders whether a simple explanation could not be given of means of calculating, at least approximately, the relation between winding, size and weight, horse-power and speed. The average amateur is, perforce, content to adopt instructions given by the makers of the castings, or advised in the query columns of journals devoted to model building; or else to depend on chance. If he could be shown how to design his windings, the interest and value of building and testing the machine would be much increased.

A few tables showing the weight of various sizes of wire accommodated in various spaces, the number of laminations of various thicknesses per inch, and so on, would be a valuable addition. Chapter XI, dealing with motor-starters, is cursory: the author explains how to calculate the total starting resistance, but then recommends that it be divided into equal sections: personally, we should not consider this advisable in a 2-H.P. starter, and, in any case, the advantage and method of proper grading should be explained. The final chapter on testing dynamos and motors for faults is thoroughly good. The book is well indexed, well produced, and to be recommended as an excellent investment to all readers, whether amateur or professional, interested in building small dynamo-electric machines.

Clock Repairing and Making. By F. J. GARRARD. London: Crosby Lockwood & Son. Price 4s. 6d. net.

As a thoroughly practical treatise, of value to the amateur as well as to those in the trade, this book deserves high Difficulties which are likely to be met with in the repair of clocks of various kinds are clearly pointed out, and the methods of overcoming the same are equally clearly explained. The writer is one who has had practical experience of the whole subject he deals with, and the numerous "wrinkles" which are so useful in mechanical work of the kind are freely given. Here and there, however, there are indications that the writer accepts common practices without questioning their correctness. On page 2, for example, he states that the bob of a pendulum is lens-shaped for the purpose of enabling it to cut the air easily. That this is purpose of enabling it to cut the air easily. the intention is doubtless true, but that that particular shape actually accomplishes the desired result is, we think, rather doubtful; probably no one has thought it worth while to question the correctness of the supposition, which, after all, is of negligible importance.

On page 126 the statement is made, in reference to turret clocks, that "steel lines if put on wooden barrels cut the wood to pieces." To this statement we can, from practical experience, give an unqualified denial, for the lines merely dig slightly into the wood and form a spiral groove; such a practice is, it is true, not one to be recommended, but it

certainly is not a disastrous one.

In regard to the dissertation on page 3 in reference to Pallets and Crutch," it is much to be desired that the most unsatisfactory arrangement of providing practically no adjustment for setting the pallets in the position to give a correct beat has not been got rid of; a few better-class clocks have two adjusting screws (page 149), but in the great majority of cases the crutch (of springy wire) has either to be bent by means of a pair of pliers, or the pallets twisted round on their axle, to which they are secured spring tight, or rather spring loose, in many cases. Again, anything more absurd than the way in which clock cases are made it is difficult to imagine; they seem to be designed with the express purpose of making it impossible to get at any part of the works for cleaning or adjustment. Clock makers or clock repairers seem to have resigned themselves to the stereotyped designs, or rather want of design, and in explaining how to take a clock apart and put it together again, point out difficulties which will be met with, but do not state that these difficulties arise from absurdities in the construction of the clocks. Mr. Garrard treats of clocks as they are, and anyone reading through Chapter II, which deals with "cleaning a skeleton clock," cannot but be struck with the completeness with which he treats the subject. Chapter III, on "Clock repairing," is full of useful information. In Chapter IV, in referring to "drills," Mr. Garrard states that "a drill is not a difficult thing to make," but such information as he gives as to how this is to be accomplished is most incomplete, and anyone desiring definite information is hardly likely to be satisfied with being told that the drill "may then be filed up to the correct shape," no information whatever being given as to what thiss hape shall be. The statement on page 127 that turret clocks should be "boxed in free from damp" is entirely wrong; what is wanted is the freest possible circulation of air through louvres, and no "boxing in"; this was pointed out by Lord Grimthorpe many years ago. We are pleased to note that Mr. Garrard considers that electric clocks have a large future before them, though he does not go into the subject at any length, this being beyond the scope of the book. In spite of the occasional incompleteness of information, the work, as a whole, is one strongly to be recommended to all those who are interested in clock making and repairing; it may be studied with very great profit, especially by country clockmakers, whose knowledge of their trade is, in a multitude of cases, deplorably incomplete, to say the least.—H. R. K.

Dinner.—The employes in the switch works of MESSES. FERRANTI, LTD., of Hollinwood, have just held their first annual dinner at the Star Hotel, Failsworth. Mr. Torrance, works manager, presided.

#### ELECTRICITY APPLIED TO MINING.

[The following discussions took place on the paper read by MB. C. P. SPARKS before the INSTITUTION OF ELECTRICAL ENGINEERS; see page 454.]

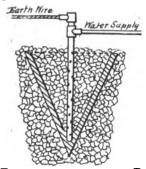

#### DISCUSSION AT NEWCASTLE.

Mr. J. LEGGAT said that even where local collieries had their

Discussion at Newcastle.

Mr. J. Leggar said that even where local collieries had their own generating plant it very frequently paid them to arrange for a stand-by supply from the local supply companies, and they were thus able to dispose of surplus energy if they produced any. He assumed that the Ilgner sets were installed on account of the comparatively small size of the generating plant, and that had the generating plant been of much larger capacity, ordinary induction motors would have been used, either coupled direct to the winding drums or geared.

Dr. W. M. Thornton said that he noticed that the disposal of the small coal was given as the reason for installing gas engines, and he would be glad to know if the "Bettington" boiler had been considered, as this was giving wonderful results elsewhere. He regretted that no costs were given in the paper, as the inclusion of these would have strengthened the case for electrical driving very considerably. He had come across several cases of protective devices acting without any fault being discoverable on the cable, and assumed that faults occasionally sealed themselves up. The duration of such faults was comparable with the duration of surges. For earth plates, he suggested a design consisting of an inverted hollow cone, as shown in the accompanying sketch; if provision were made to run water into this cone it would provide a continuous source of moisture for the surrounding coke. Due attention had not been paid to the effects of the comparatively large inductance of the ordinary mining electric bell. With the amount of inductance due to an electric bell in the circuit, the ordinary currents in use could undoubtedly cause explosions. He did not consider the figures at the end of the paper accurate enough to be put forward as authoritative. There was no doubt whatever that mixtures of pit gas could be ignited when using present-day voltages. With alternating currents, a higher percentage of gas was necessary to obtain the maximum explosive effect. The only way out

METHOD OF EARTHING SUGGESTED BY DR. THORNTON.

tween the motor pinion and the spur-wheel on the haulage; this would lengthen the bed-plate somewhat, but would obviate the somewhat unmechanical extension bed-plate for the motor where it had to be placed alongside of the haulage. Turning to the generating plant, he noted that the nine turbo-generators were made by no fewer than four firms, the alternators by four firms, and there were six different combinations of complete sets. Reading between the lines, it appeared that the gas engines had not been much of a success, and he saked why it was that these large gas engines were so successful abroad, and so unsuccessful, as a rule, in this country. He considered that a weak point in the Coal Mines Act, 1911 (General Regulations of July, 1913) was in insisting upon a surface earthplate without at the same time insisting upon earthplates at each level, as it had been shown conclusively by Mr. W. Wood that very dangerous conditions might arise with a surface earthplate only, due to insulating strata intervening between the surface and the various levels. Mr. Sparks's recommendation to earth the neutral point in every case was decidedly too sweeping; colliery managers and electricians held that an earthed neutral was not necessarily better than an insulated neutral. It was highly dangerous to make it possible for an automatic protective device to plunge a whole pit into darkness, and where separate lighting cables were installed, to be consistent, these should also have automatic leakage protection, with possibly disastrous results in the event of an earth occurring. With regard to underground lighting, he did not consider that rubberinsulated cables run in screwed tubing made a satisfactory job. He suggested the use of cab tire-sheathed cable for this work. With regard to the cost of running miners' electric lamps, the cost of lamp bulbs averaged 0.12d. per lamp per

shift, whereas no lead cell on the market could be run for much less than .3d. per lamp per shift. It was, however, a fact that when using alkaline cells the cost of battery maintenance just equalled the cost of lamp-bulb maintenance.

Mr. H. W. Clother thought that it was better to eliminate lightning arresters altogether. With regard to the objection that automatic leakage protective devices might cause danger by plunging a pit into darkness, he suggested the use of a number of these devices at different parts of the system, so graded as to cut out the defective part only. He suggested that relays might be used in connection with signalling systems, as these could be made to work with very minute currents; in one case he had in mind the power required did not exceed 0.08 volt-ampere He did not agree with Dr. Thornton that the figures given at the end of the paper were unsatisfactory, because they formed a faithful record of some-

Thornton that the figures given at the end of the paper were unsatisfactory, because they formed a faithful record of something which was not known before.

Mr. P. V. HUNTER said that in considering the results of a colliery electrification one could generally state whether or not the advice had been good by noting the power factor, and from the excellent results shown in the paper it was apparent that the Powell Duffryn scheme was a well-designed one, with motors properly proportioned for their work. He quite agreed that for the installation under consideration fifty cycles was much better than twenty-five cycles. He joined issue with Mr. Sparks on the question of burying the earth plates at a great depth; a much better arrangement would be to have a

Mr. Sparks on the question of burying the earth plates at a great depth; a much better arrangement would be to have a multiplicity of earth plates. To provide an efficient earth for static sub-stations it had been found necessary to provide no fewer than eight plates placed 40 ft. apart and carefully bonded together.

Mr. C. P. Sparks, in reply, said that the special ventilating arrangement shown in connection with the Elliot Pit pumping station had been found necessary owing to the high temperatures attained by the atmosphere in the pump-room and to guard against accumulations of coal dust. He took exception to Dr. Thornton's remarks that the tests on ignition by signalling wire were not scientific, as an elaborate series of tests had been very carefully made. The gas engine installation had not been a failure, and the company were increasing the number of gas engines. The variety of types of machinery was accounted for by their trying to eliminate faults discovered in existing plants.

#### DISCUSSION AT BIRMINGHAM.

Mr. R. A. Chattock said that it was interesting to find that the gas-driven generators required 18 B.Th.U. per watt-hour against 36.5 for the live steam turbines. This difference was largely accounted for by the difference in the load factor governing each type of generating plant, the gas plant having a load factor of 72 per cent., whilst the steam only had 47 per cent. Even better figures than those given should have been obtained with such load factors. It was certainly very necessary to keep the load factor on the gas-driven plant at the highest possible point, and it was interesting to see that in mining work it was possible to adjust the load by carrying out the pumping during the night time and supplying the general colliery demands during the day, and thus to obtain an annual load factor of 72 per cent. Some years ago he went into the question of using gas plant compared with steam turbines for ordinary electric power supply from a central station, and he was satisfied that an annual load factor of at least 35 per cent. would be required before the gas plant could compete with the steam turbine. The ordinary central station, working on light, power and traction load, had only a load factor of about 25 per cent., and the adoption of gas-driven plant was therefore not justified. These conclusions were based not only on the actual cost of generation by the two methods, but also on the capital cost of the plant and buildings required; in addition, he considered that turbine-driven plant was more reliable than large gas engines, experience with which had not, up to the present, been entirely satisfactory.

Mr. N. Shuttleworth said that the Ilgner motor-generator Mr. R. A. CHATTOCK said that it was interesting to find that

with which had not, up to the present, been entirely satisfactory.

Mr. N. Shuttleworth said that the Ilgner motor-generator sets described in the paper were probably the second largest in the Kingdom. As with all other sets of a similar kind, it was necessary to arrange for a considerable drop in speed between no load and full load on the induction motor, so that excessive demands made on the c.c. generators could be provided by the flywheel at the expense of its stored energy. The methods in use for enabling this speed drop to take place as the load increased were as uneconomical as it was possible to imagine. In the present instance a resistance was inserted in the secondary circuit of the induction motor which absorbed at maximum slip or minimum speed some 15 per cent. of the total input to the motor. The average slip in the absence of further particulars might be assumed as 8 per cent., which meant that 8 per cent. of the continuous input to the induction motor was wasted. The liquid slip regulators which consumed this energy required considerable attention to the induction motor was wasted. The liquid slip regulators which consumed this energy required considerable attention and were expensive to keep in good repair. He would suggest the use of a rotary slip regulator, which took the form of a commutator motor inserted in the slip-ring circuit of the induction motor to be regulated. Making allowances for the losses in the rotary regulator, some 7.5 per cent. of the present input to the induction motor would be saved. Moreover, the power factor of the induction motor would be improved at the same time practically to unity, so that on the whole

the supply current would show a reduction of approximately 20 per cent. Incidentally this also improved the efficiency of the system because the colliery plant was fed by transmission lines of considerable length in which the losses inclusive of step-up and step-down transformers would not be less than 7 per cent., and by reducing the line current by 20 per cent. the transmission losses were reduced to 4.5 per cent. The rotary regulator could, therefore, be said to save no less than 10 per cent. of the present input and at the same time increase the carrying capacity of the transmission system. On the basis of cost of power of one penny per ton of coal raised to the surface, the saving for both winders amounted to 6s. per working hour, or probably £5 per day. It would seem, therefore, that the direct benefits to be obtained from the use of a rotary type regulator amply instified further capital amounts. rotary type regulator amply justified further capital expenditure in this direction.

Mr. C. Jones gave particulars of electrical apparatus which he had installed at Cannock Chase Colliery, and emphasised the large field which was open to electrical engineers for elec-

the large field which was open to electrical engineers for electric haulage to perform the work now done by pit ponies.

Dr. C. C. GARRARD, in speaking of flame-tight boxes for electrical apparatus, pointed out the advisability of always carrying out the tests with coal gas, as this was a more highly explosive gas than the gas found in mines, and consequently if the boxes were safe with coal gas they could be relied upon to give complete protection in service under mining conditions.

#### DISCUSSION AT MANCHESTER.

Mr. SEATON stated that Lancashire would very shortly pos-

Mr. Sealon stated that Lancashire would very shortly possess a thoroughly up-to-date colliery electrically equipped throughout and with steam turbines as prime movers.

Mr. W. T. Anderson said it was remarkable that all fatal accidents in connection with electricity below ground were due, not to unearthed systems, but invariably to high resistance in the earth circuit. It was most difficult to convince colliery managers and engineers of the importance of earthing. Generally speaking, earthing consisted of putting an 18 in. earth plate into the ground, and if a bell rang through it all was considered well. Heavy earth plates buried in made was considered well. Heavy earth plates buried in made ground were invariably used, and in his opinion were a source of considerable danger. He described a system of earthing adopted at the Clifton and Kearsley coal mines in which castiron pipes 9 ft. long by 9 in. diameter, were buried vertically in a pit which was constantly supplied with water. Recent tests showed a resistance of 3.8 ohms between duplicate sets of pipes and 1.48 ohms between pipes and sets in parallel. The 50 per cent. conductivity in metallic sheathing demanded by the Rules was in his experience almost impossible with by the Rules was, in his experience, almost impossible with joints. Earthing of neutrals was very necessary.

Mr. G. M. Brown said that the Powell Duffryn property was ideal for complete electrification. The greatest drawback

was ideal for complete electrification. The greatest drawback was the low average power factor, due largely to the enforced use of low-speed motors of great overload capacity. In the case of the Aberdare Valley the average was between .7 and .85, probably nearer .7 in cost cases. This was inevitable in colliery work, owing to the necessity of having haulage motors of ample capacity for their work. These motors usually represented a large proportion of the total load. Static condensers could be used in the case of small motors to keep the power factor at its maximum value at practically all loads and speeds, and in the case of large motors running under very steady and in the case of large motors running under very steady load, the phase advancer could be used. The disadvantages of the phase advancer were that it could not be kept in circuit of the phase advancer were that it could not be kept in circuit on starting or reversing, and that the amount of leading wattless current was unduly large in proportion to the motor load. These disadvantages effectually barred its use in connection with haulage motors, and the best method appeared to be the installation of a synchronous condenser. A simple calculation would show that the so-called wattless load of the Powell Duffryn Co. represented a capital value of several thousand pounds, and if to this was added the probable cost of generator and transformer capacity to deal with this load, the total would be astounding and would demonstrate the fact that an investment in plant for improving the power factor on transmission lines would be a sound financial proposition.

Mr. H. W. Edmondson said, referring to portable lamps, that half-watt lamps would probably be used, but not in the near future. The exact voltage conditions under which portable lamps would be used should be ascertained in order to ensure efficient working.

Mr. S. I. Watson said that as for an about it is the second to the said that a said that a said that a said that as for an about it.

mr. S. J. Warson said that as far as electrification of collieries in Lancashire was concerned, practically the whole field had got to be attacked. Gas engines were a thoroughly

held had got to be attacked. Gas engines were a thoroughly good proposition at a centre where coke ovens were installed. It would be of interest to know why on a transmission line only nine miles long, it had been necessary to step up from 10,000 to 20,000 volts.

Dr. G. W. Worrall, referred to earth resistance tests which he had superintended at a large group of collieries. The conductivity of the earth return varied from about 1 to 21 times the conductivity of the cable. The result depended upon the size of cable, and also took account of joint boxes and the size of cable, and also took account of joint boxes and switchgear which were installed. Regarding the resistance of earth plates, some tests carried out by him using two auxiliary earth plates showed a resistance slightly under one ohm. Colliery managers seemed to think that when installing a 20 or 30-H.P. haulage motor it was simply recognized to the a 20 or 30-H.P. haulage motor, it was simply necessary to cut

a hole in the aide of the shaft and put the motor there. Open a note in the aide of the shalt and put the motor there. Open fuses and switchgear which did not conform to Home Omce regulations were frequently met. The engineer of a very large group of collieries advocated the abolition of all starting gear underground; specially designed motors of about 40 H.F. were switched direct on the mains, and the results were stated to be very satisfactory. to be very satisfactory. He suggested that miners' lamps should be fitted with reflectors instead of leaving the lamps open; this would enable anyone following the bearer of the lamp to see ahead much better. Leather thongs for suspending cables were usually eaten away by rats and had to be replaced by zinc thongs.

Mr. C. Day said the utilisation of exhaust steam had grown Mr. C. Day said the utilisation of exhaust steam had grown enormously, one company having supplied over one hundred plants for this purpose. The problem of condensing plant in collieries was a difficult one; corrosion and sediment problems were common, and it seemed quite the thing that jet condensing plant rather than surface plant with tubes should prevail. Taking 100 cases in his experience, only one-fourth were surface condensing, the remainder being of the jet type. Corrosion was more prevalent with the very high speeds of rotation than with the lower speeds; it was a distinct fact that a centrifugal pump run at 3,000 revs. would be more likely to show corrosion than if run at 1,000 revs. Therefore, if small steam turbines were used for driving these Therefore, if small steam turbines were used for driving these pumps it would seem better to drive through gears and keep

pumps it would seem better to drive through gears and keep the speed of the pump down.

Mr. Nelson considered the question of colliery staff very important. Colliery plant was installed and when running all right was handed over to a man who, in view of the small size of the colliery, could not be adequately paid and therefore could not have the experience to deal with such a valuable collection of machinery. This point alone warranted the aunthy being taken from a company. able collection of machinery. This point alone warranted the supply being taken from a company. Regarding motors, he advocated the specification of a certain air gap, as in many cases very high efficiencies and high power factors were demanded necessitating small air gaps, with consequent trouble due to slight wear of bearings. There was considerable room for improvement in the arrangements for easily and speedily removing connecting cables from portable haulage motors and the operating gear.

Mr. E. C. McKinnon said regarding positive battery plates it was stated that the original lead type lasted about nine months; assuming six charges per week this would work out at about 200-250 charges. The life of the plate was affected by too much charging, but the deterioration could be decreased by the use of celluloid separators between plates. Care of the positive plate would give at least 600 charges instead of the present maximum of 250.

Mr. W. Cramp said it was difficult to realise how it would

Mr. W. CRAMP said it was difficult to realise how it would Mr. W. CRAMP said it was difficult to realise now it would pay a colliery to buy its current unless the colliery were very small. Comparative figures would be interesting, even if actual figures were withheld. The author had stated that trouble had arisen due to pre-ignition, and for that reason the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colling of the colli the powers of the gas engines were reduced; there appeared to be other means of overcoming this trouble. The compression be other means of overcoming this trouble. The compression could be reduced, which would enable the gas engine to work again up to its full power. Another arrangement was to draw in with the air a certain amount of the exhaust gases ejected from the cylinder, which reduced the richness of the mixture and prevented pre-ignition. It had always been a puzzle to know why for 1,000 K.V.A. units the low-speed engine was adopted at all. The cost per kw. was particularly greater than that of the high-speed vertical engine; in fact two vertical sets could almost be bought for the price of one horizontal set. Besides the engine cost, there was the enormous cost of low-speed generators compared with the small cost of direct-driven high-speed generators. A third and not altogether negligible factor was that the high-speed vertical engine was a home product and could be built and repaired here. For the air filter a pressure of 4 in. or 6 in. of water produced by the fan was quite unnecessary; an inch at most should be sufficient.

Mr. Sparks said that one point in the paper was unani-

be sufficient.

Mr. Sparks said that one point in the paper was unanimously approved in London and at the Local Sections, viz., the earthing of the neutral. Mr. Anderson had shown how by careful design and good construction earth resistances of 3.8 and 1.48 ohms could be obtained. He desired to impress upon all members the fact that this earthing matter could not be dealt with haphazard, because, after all, the earth connection was intended to be the main safety point. The sheathing could not be relied upon, and in the paper an actual conductor was advocated. The author advised a number of smaller collieries not so favourably situated as Powell Duffryn, and it appeared simpler for them to purchase from power companies the moderate amount of energy they required. newer companies the moderate amount of energy they required. He did not know of a power company which could supply such an undertaking as the Powell Duffryn. Mr. Edmondson's remarks regarding lamp voltage embodied an exceedingly valuable suggestion; it was often overlooked that what appeared in itself a small variation in voltage was a large percentage when dealing with a 2-volt lamp. They had started appeared in itself a small variation in voltage was a large percentage when dealing with a 2-volt lamp. They had started with a surface condenser, but owing to the large amount of oil etc.. coming from the winding engine, and through the low-pressure system into the condenser, the difficulty of maintaining a good head with surface condensing was very great, and in the latest adaptation a jet condenser had been used. In Day's recommendation of the jet condenser was about the property right, as surface condensing was too difficult a makkey. lutely right, as surface condensing was too difficult a problem to keep up. When the winder-house was put up it was in-

1.5

tended to put in one electric crane, but as it was required to erect the plant quickly, it was arranged to build the workshop exactly the same width as the winder-house, as it only meant altering the building by a foot or two. The original two cranes were therefore available for the winder-house during erection, and subsequently one of the cranes was transferred to the pump-house. The scheme saved an enormous amount of time and money. For many years he had always demanded in specifications to have the air gap dimensions of the motor. There was a reason why vertical gas engines had been ignored. It was desired at the start to go in for a unit of about 1,500 kw., and at that time, eight years ago, it was quite incredible that a firm should consider a high-speed unit delivering anything like 1,500 kw., and although there was some approval of the proposal, no bids could be obtained for a unit of this size. This was the reason for the low speeds. Improvement in power factor was attained by working at a fixed pressure. Motors designed to give good results at 3,000 volts would have a good power factor at 3,000 volts, but if the voltage was 2,900 or appreciably over 3,000, the power factor would be bad.

# IMPORTS OF HOLLAND.

THE following figures showing the imports of electrical and similar goods, for consumption, into Holland during the year 1913, are taken from the recently-issued official trade statistics; the figures for 1912 are added for purposes of comparison, and notes of any increases or decreases are given.

# UTILISATION OF WATER-POWER.

IN a paper read recently by MR. ARTHUR SURVEYER, before the CAMADIAN SOCIETY OF CIVIL ENGINEERS, the author dealt with the question of making Canadian water-powers valuable, and incidentally touched on electrochemical and metallurgical developments in connection with hydro-electric power. A brief abstract of his repressing a follows.

of his paper is as follows:—
The following table has been compiled from various European sources, from the reports of the United States Geological Survey and from the report of the Canadian Cummision of Conservation. It shows the total available and developed water-powers in the different countries of Europe, in the United States, and in the various Provinces of Canada; it also indicates the percentage of utilisation for each country and the horse-power per sq. mile.

The data contained in this table refer to conditions in the year 1911, and the provincial areas used to calculate the figures of

year 1911, and the provincial areas used to calculate the figures of the last column are taken from the Canadian Arlas of 1906.

It would have been more interesting if complete figures for 1914 had been available. Unfortunately, nothing authentic could be obtained except in a few instances. The inclusion of the new Shawinigan development, the Canadian Light & Power Co.'s shawinigan development at Cedars would raise the figures plant, and the large development at Cedars would raise the figures for the Province of Quebec to over 500,000 developed horse-power. Switzerland's present figures are about 550,000 H.P., Norway's over

1,000,000 H.P., and those of the United States between 5,500,000 and 6,000,000 H.P.

It is probable that the data concerning Europe and the United States are fairly accurate, whilst the Canadian figures are based on doubtful information. The Conservation Commission of Canada in its report of 1911 did not "consider advisable to make an estimate of the total water-power in Canada," adding, "one estimate places it at nearly 17,000,000 H.P.; but it does not, and cannot, rest upon any basis of reliable information."

Table II and Table III refer more closely to the subject of this paper and supplement to a great extent the information given in

TARLE II

TADOB II										
				Sub-division of developed power.						
Provinces.		Developed power.	Electrical energy.	Pulp and paper.	Various Industries.

<b>Qaebe</b> c	•••	•••	328,000	1 <b>98</b> ,00 <b>0</b>	88,000	42,000				

Table II has been compiled from the report of the Canadian Commission of Conservation, and details the uses made of the developed water-powers in Oatario and Quebec. It should be noted that 74,000 electrical H.P. are exported from Ontario to the United States at Niagara Falls, and this amount is, therefore, not included in Table III.

Table III.

Table III indicates the uses made of the hydro-electric energy generated in Ontario, in Quebec, in France, in Sweden, and in Norway. The data for the Provinces of Ontario and Quebec were taken from a paper by Mr. Watson Bain on the "Electrochemical Industries in Canada." The figures for the other countries refer to the contribution of the countries refer to the countries of the countries refer to the countries refer to the countries refer to the countries refer to the countries refer to the countries refer to the countries refer to the countries refer to the countries refer to the countries refer to the countries refer to the countries refer to the countries refer to the countries refer to the countries refer to the countries refer to the countries refer to the countries refer to the countries refer to the countries refer to the countries refer to the countries refer to the countries refer to the countries refer to the countries refer to the countries refer to the countries refer to the countries refer to the countries refer to the countries refer to the countries refer to the countries refer to the countries refer to the countries refer to the countries refer to the countries refer to the countries refer to the countries refer to the countries refer to the countries refer to the countries refer to the countries refer to the countries refer to the countries refer to the countries refer to the countries refer to the countries refer to the countries refer to the countries refer to the countries refer to the countries refer to the countries refer to the countries refer to the countries refer to the countries refer to the countries refer to the countries refer to the countries refer to the countries refer to the countries refer to the countries refer to the countries refer to the countries refer to the countries refer to the countries refer to the countries refer to the countries refer to the countries refer to the countries refer to the countries refer to the countries refer to the countries refer to t to conditions previous to 1910, and have been compiled from different statistics. The conclusions resulting from the examina-tion of Table III are that up to the present we have only progressed in the more simple applications of electricity, and that we have practically neglected its utilisation as an electrolytic agent and as a heat generating agent in electrochemistry and electrometallurgy.

TABLE III.

Countries.		Domelened	Sub-division of developed power.							
		Developed hydro- electric power.	Electro-che and electro-met	•	Motive power, Traction and lighting.					
		н.р.	H.P.	%	н.р.	%				
France	•••	592,000	291,000	49'1	301,000	50 9				
Norway	•••	543,000	275,000	50.6	268,000	49'4				
Sweden	•••	370,000	120,000	32 4	250,000	67.6				
Ontario	•••	320,000	25,000	78	295,000	92.2				
Quebec	•••	198,000	28,000	14.1	170,000	85.5				

It is self-evident that the consumption of electricity for lighting or for traction depends on population. Neglecting the Montreal market, which is exceptional, the consumption of electricity per capita either for lighting or for traction is too small to be considered as an inducement to the extensive development of our waterfalls. A Western statistician gives the consumption of elecricity in small towns as, roughly, one-tenth of a horse-power per inhabitant, so that a plant of 1,000 H.P. would, on this basis, be sufficient to supply the requirements of a town of 10,000 population. On the other hand, the smallest electrochemical or electrometallurgical industry consumes more than 1,000 H.P. Plants of 10,000 H.P. are numerous, and those of over 30,000 H.P. are by no means exceptional.

The pulp and paper industries are also great users of power, but we in Canada are not so very far behind in this phase of develop-

ment, although Sweden utilises over 120,000 H.P.

An improvement in the situation might be brought about by attracting to Canada more electrochemical and electro-metallurgical industries, thereby causing a notable increase in the development of our water-powers. It has been thought advantageous to briefly rayiew some of the industries which, either on account of the abundance of the necessary raw materials, or because of the large neighbouring markets, might be likely to prosper in Canada.

#### ELECTROCHEMISTRY.

Carbide. -The calcium carbide industry was started in 1895, with Mr. Wilson, of Ottawa, as one of the pioneers. There are now over 70 plants situated all over the world capable of absorbing 360,000 H.P. in their operation. The world's production for 1910 was 250,000 tons; it was 300,000 tons in 1912, and increased to 340,000 tons in 1913.

One special feature of the carbide industry is that many of the producing countries are not users of the product, and that the centres of consumption are located in places where it is impossible for want of waterfalls to manufacture carbide.

Germany, England, Australia, and the South American Republics are the importing countries; the consumption of Germany has increased five-fold in the last 14 years, having risen from 11,000 to 55,000 tons annually. The exporting countries are Sweden, Norway, Switzerland and the United States. The production of the United States in 1913 was 70,000 tons, with an export trade of

The American exports go to South and Central 15,000 tons. America, where the demand for acetylene for house lighting is rapidly increasing.

Nitrate of sods, or Chile saltpetre, is the best known of the imported fertilisers; it is found in its natural state in immense deposits situated in Chile, Peru and Bolivis. The curve gives an idea of the phenomenal increase in the world's consumption.

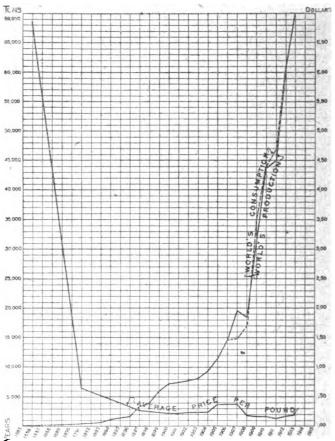

Nitrate of Lime. - Nitrate of lime was not at first received with Average of Lime.—Nitrate of lime was not at first received with favour by the farmers on account of its hygroscopic properties which demand the inhmediate use of the whole contents of a barrel once it has been opened. However, outside of this inconvenience, nitrate of lime has been proved entirely superior to the Chilian nitrate of sods, and its consumption as a fertiliser has increased rapidly.

The manufacture of synthetic nitrate of lime has only been carried out so far in Norway by the Norwegian Nitrogen Co., and its subsidiary companies, grantees of the Birkeland and Eyde and

Schonnberr patents.

The chemical fertilisers manufactured at Notodden are nitrates of lime, of potash, of ammonia, of phosphate of ammonia, and of biphosphate of lime; this industry produces also nitric acid and nitrite of soda. The production of nitrate of lime was 9,500 tons in 1909, and it is estimated that the production in 1915 will be about 160,000 tons.

The Norwegian Nitrogen Co. and its subsidiary companies have undertaken, solely for the needs of this industry, the construction of a number of hydro-electric plants, the total capacity of which will reach the enormous figure of 540,000 H.P. There are at present four plants of approximately 180,000 H.P. in operation, with two others totalling 160,000 H.P. in course of construction.

PRODUCTION, CONSUMPTION AND AVERAGE PRICE OF ALUMINIUM.

The world's yearly consumption of nitrate of soda is approximately 2,500,000 tons; but the Chilian saltpetre is not utilised solely as a fertiliser, it is also employed in the manufacture of powder and nitric acid. It is generally acknowledged that industry does not absorb more than t or t of the total production of nitrate of soda.

Mr. E. F. Côte, a well-known French economist and engineer, after having analysed the progress of the different Norwegian industries in 1912, expressed the following opinion concerning the future of the manufacture of nitrate of lime

"Four hundred thousand horse-power with the efficiency mentioned above would probably produce 250,000 tons of nitrate. But what is this? Chile exports every year 2,000,000 tons of natural nitrate to Europe; in 10 or 15 years the Norwegian nitrate plants will have attained their full development; but their production then will not be sufficient to take care even of the increased consumption. It is certain, on the other hand, that the Chilian beds will not be able to indefinitely supply the rapid and continuous increase of the demand, and it will be necessary for industry to develop its own means of production in order to satisfy the urgent need for nitrogen of the bread-eating nations. This means that the market for nitrogenised fertilisers is practically unlimited and that is why the capitalists have given their backing to the electrosynthetic processes with a spontaneousness which has only been equalled by their boldness."

Limestone is the only raw material required in the manufacture of nitrate of lime, the economical production of which is entirely dependent on the cost of the electrical energy. In Norway, the cost of production of nitrate of lime is very much below the selling price of Chile saltpetre.

Nitric Acid.—Synthetic nitric acid is chiefly obtained by the

Nitric Acid.—Synthetic nitric acid is chiefly obtained by the Pauling process, which is similar in principle to the Birkeland and Byde, and Shonnherr processes.

The Pauling furnaces are used in Austria-Hungary, at Patsob, near Innsbruck: there are 24 furnaces absorbing 15,000 H.P. Another plant of 8,000 H.P. operates the Pauling process in the north of Italy, whilst in France, the Roche-de-Rame works near Briar con, have utilised 8,000 H.P. since 1908, and will ultimately use 20,000 H.P. mately use 20,000 H.P.

mately use 20,000 H.P.

Nitric acid manufactured synthetically is very pure, and is free from nitrous products, and from chlorine and sulphuric acid.

The world's production of nitric acid is from 200,000 to 250,000 tons per year, Germany producing about 100,000 tons, and the United States 70 000 tons per year. The margin between the selling price of ordinary nitric acid and the cost of synthetic szotic acid is large and indicates that this industry can afford to pay

more for its electrical energy than the ritrate plants.

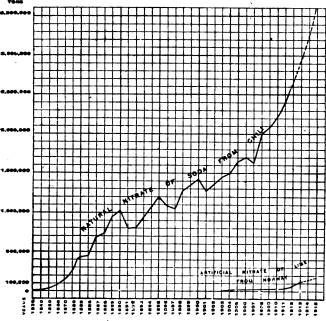

Culcium Cyanamide.—This is an artificial fertiliser containing carbon, nitrogen and calcium.

Electrical energy is used chiefly in the production of calcium cyanamide, which is the raw material, and which is transformed chemically into an azztised compound.

Calcium cyanamide is manufactured in 15 different plants located in France, Switzrland, Norway, Italy, Austria-Hungary and Japan. In addition, the American Cyanamide Co. has important works in the State of Alabama, and a plant at Niagara Falls on the Canadian side.

The world's production in 1911 was 110,000 tons, in 1912 was 153,000 tons and in 1913 reached 226,000 tons.

The Canadian plant began operation in January, 1910, with a

PRODUCTION OF NITRATES IN CHILE AND NORWAY.

yearly capacity of 10,000 tons; in March, 1913, the production of

the plant had been increased to 24,000 tons per year.

Aluminium.—This is manufactured by electrolysing alumina dissolved in a molten bath of cryolite, these materials being placed in an iron trough lined with carbon, and connected to the negative pole of a dynamo, while a carbon anode immersed in the charge is connected to the positive pole.

Alumina is obtained by refining bauxite; this ore is composed of impure hydrated alumina, and contains besides ferric oxide, silicon and titanium oxide. France and the United States are the countries rich in bauxite. In 1910 the world's production of banxite was 271,000 tons, and of this total France had supplied 128,000 tons and the United States 129,000 tons.

In 1912 the United States produced 165 000 tons of bauxite, and imported 27,000 tons from France. They exported in the same year to Canada 10,000 tons of alumina or concentrated bauxite. The cryolite employed in the metallurgy of aluminium is a double fluoride of aluminium and of s.dium. The only known deposit is situated in Greenland, and belongs to the Danish Government. The export of this natural cryolite had reached 8,000 tons ment. The export of this natural cryolite had reached 8,000 tons in the year 1911. However, the double fluoride of aluminium and sodium is now prepared artificially in France and in Austria; the raw material used in this manufacture is the fluoride of calcium and the arms that a graph is in considered a comment. called fluorspar, and the synthetic cryolite is considered a much better product than the natural cryolite of Greenland.
Since 1886 the increase in the world's consumption of aluminium

has been phenomenal. The chart shown indicates this rapid rise,

and also shows the corresponding drop in the selling price of the metal.

The manufacture of aluminium was towards 1890 in the hands of five companies, who raised the production of aluminium from 175 tons per year to 7,300 tors during the period from 1870 to 1890. In 30 years the average price of aluminium decreased from

\$1 a lb. to \$0.22 a lb. in 1900.

The price of \$0.22 per lb. did not leave a very great margin of profit, so that in 1900 the five companies amalgamated into an international syndicate to regulate the production and the selling

price of aluminium.

This combine caused an immediate rise in the quotations, but in 1907, the patents for the manufacture of aluminium having become public property and the price of copper having fallen very low, the production of aluminium became much larger than the demand for it. This was followed by a crisis, which brought about the dissolution of the aluminium syndicate in 1908.

In April 1911 a new alliance was formed between the different.

In April, 1911, a new alliance was formed between the different manufacturers of aluminium. The object of this combine was to regulate the selling price, to put a stop to the cut-throat competition which had existed since 1908, and to work for the constant

enlargement of the market for aluminium.

The extraordinarily low prices of aluminium have resulted in the popularising of the use of the metal and the increase in its consumption in a remarkable manner, so that a return to normal conditions will leave the manufacturers who have been able to face the orisis with a market for their product definitely enlarged and continually increasing.

In 1912 the United States produced 18,000 tons of aluminium, France 13,000 tons and Canada 9,000 tons.

Zinc.—The production of zinc by the electro-thermic process has been undertaken chiefly in Sweden and Norway. At Trollhattan in 1912 11 furnaces produced 3,228 tons; the plant is to be enlarged to 17 furnaces of 1,000 HP, each and eight of 500 HP. each, giving a total installed capacity of 21,000 HP.

Two Norwegian plants produced 8,900 tons in 1912; and at Vancouver the Canada Zinc Co. is supposed to be operating several Snyder furnaces for the electro-thermic treatment of zinc.

Nickel and Copper. - Drs. Haanel and Héroult have experimented

Nickel and Copper.—Drs. Hasnel and Héroult have experimented at Sault Ste. Marie, and think it would be possible to obtain commercial ferro-nickel pig by the electro-reducing process.

In 1910 the total power used by aluminium works was over 320,000 H.P., of which 140,000 H.P. was developed in France.

The actual capacity of the plants of the Aluminium Cc., of America, is 90,000 H.P., and this company has signed a contract for the purchase of 60,000 H.P. for use at its Messena Works on the St. Lawrence.

The Sharinian Falls plant of the Northern Aluminium Co. here

The Shawinigan Falls plant of the Northern Aluminium Cc. has a capacity of 20,000 H.P. A French company, the Southern Aluminium Co., has started at Whitner, N.C., the construction of a 70,000 H.P. hydro-electric plant, with furnaces, &c., which was to

The Government of Chile has also been making extensive experiments in France on the industrial production of copper, and hopes to be able to effect a reduction of 75 per cent. in the cost of its production by means of the electric furnace.

Production of Pig-Iron by the Electric Furnace.—In 1906, the Canadian Government authorised Dr. Haanel to experiment on the reduction of ore in the electric furnaces known at the time. The experiments were followed by experiments in Sweden extending over several years. At Domnarfyet, the tests took place between 1907 and 1909, and were made with several small furnaces which had been invented by three Swedish engineers.

The Swedish Association of Iron Masters considered that the results of the operation of the Gronwall furnace were good enough to warrant the construction in 1910 of a complete experimental plant at Trollhattan near the Government's hydro-electric plant. The Trollhattan experiments were continued until September, 1911, and were made in a furnace of 3.000 H.P. The new electric blast-furnace of Domnarfeet is of 12,000 H.P. and should produce

100 tons of pig-iron per day.

Iron ores are smelted by the electro-thermic process in California, in Italy, in Norway and at many places in Sweden. The production of electric pig-iron in this last country was 122 tons in 1900 against 17,600 tons in 1912. The world's production in 1912

was approximately 25,000 tons.

The Noble Electric Steel Co, of California, has in operation three

furnaces of a total capacity of 8,000 H.P. There are in Scandinavia 20 furnaces absorbing over 36,000 H.P.

Ferros.—The name "ferro" is used to designate special varieties of pig-iron which are used as a final adjunct in the metallurgy of steel. These are ferro-manganese, ferro-silicon, ferro-chrome, of steel. These are ferro-manganese, ferro-silicon, ferro-chrome, ferro-molybdenum, ferro-tungaten and ferro-titanium. The pigs produced in the electric furnace are expensive products of high quality. In 1910, according to the statistics of "l'Industrie Mirérale" the average value of ferros produced in the electric blast-furnace was \$21.00 per ton, whilst the ferros of the ordinary blast-furnace was sold at \$2.00 per ton.

Ferro-Silicon — Ferro-silicon is used in the converting of pigiron for the production of steel. The world's production is over 100,000 tons of ferro-silicon per year. Two Canadian companies manufacture this product: The Lake Superior Power Co., at Sault Ste. Marie, with an electric furnace of 250 H.P., and the Electric Metals Co. at Welland, operating four furnaces of a total capacity of 5,000 H.P.

of 5,000 H.P.

Ferro-Titanium.-The manufacture of ferro-titanium in the electric furnace is particularly interesting on account of the large deposits of titanium ore in the Province of Quebec. The United States' production of ferro-titanium for the year 1912 has been

estimated at 3,763 tons and nearly 600,000 tons of titanium-treated steel have been manufactured, as against 400,000 tons in 1911.

Production of Steel in the Electric Furnace.—The electric furnace used for the production of high and medium grade steel has so many advantages over the other furnaces that its general use

appears absolutely certain in the very near future.

There are already more than 120 furnaces in operation in the world, and the production of electric furnace steel has risen from 33,000 tons in 1908 to 175,000 tons in 1912. Germany has tripled her production since 1910, and in 1913 had in operation 15 plants producing about 102,000 tons a year, placing her in the lead of the other countries. The United States, after having manufactured, in 1910, 52,000 tons, including a large quantity of electric furnace steel rails, is now awaiting the results of the use of these rails and is only turning out in the electric furnace special high-grade steels to the amount of 18,000 tons annually.

The electric furnace is also extensively used for melting steel

for castings.

Conclusions.—The different industries which have been enumerated absorb approximately 1½ million hydro-electric horse-power, and Canada's contribution to this enormous utilisation of power is

just about 3.5 per cent. of the total.

This paper can only be considered as a very brief survey of a very large field, and it would be rash to attempt to draw from it any definite conclusions. It is evident that all the industries mentioned above would not be sure of success in Canada, and that every particular case should be studied with the utmost care before

trying to attract the investing public.

The great advantage of the water-powers of Sweden and Norway is the remarkable height of their falls and the consequent smaller

volume of water required for the same power.

It would be possible on our navigable rivers to sub-divide the cost of development between navigation and industry. This would so reduce the cost of the industrial part of development that the unit cost of these low-head hydro-electric plants might compare with the figures of the Scandinavian developments. This Government help has been given to several plants in Europe and America and explains in a measure the apparently low cost of some of their

There is no getting away from the fact, however, that the criticism of foreign engineers is partly correct. We are in a measure handicapped, and there are numerous obstacles, economical, educational and physical which interfere with the rapid development

of our water-powers.

It is significant to note that the countries which have given the greatest number of years to the technical study of their water-powers have the highest percentage of utilisation: Germany, the Scandinavian countries, France and Switzerland, for example, were the first countries of Europe to undertake the systematic study of their rivers and falls, and these nations are now getting a greater return from their natural forces than the other countries

It is only recently that such studies have been undertaken here. At present, the Canadian Public Works Department, the Department of the Interior, the Quebec Streams Commission, the Hy Electric Power Commission of Ontario, and the Province of British Columbia, have undertaken the scientific discharge measurements of some of our rivers, and have established gauges all over the country.

It is safe to say to-day, that through the lack of surveys, of discharge measurements and of gauge readings there are very few of our waterfalls which could be offered to oversea bankers.

The development of our water-powers has also been greatly handicapped by the difficulty in obtaining a clear title of ownership, and by the uncommerciality of some of the clauses contained in Government leases.

#### SCIENCE AND INDUSTRY.

It has been our privilege to attend two conferences at the Mansion House, at which the theme discussed was the need for co-operation between science and industry. One of these was held between nine and ten years ago-it was the inaugural meeting of the British Science Guild, at which the Right Hon. R. B. Haldane was elected first President. Interesting speeches were delivered by men of unquestioned eminence—a Bishop, an Admiral, engineering leaders such as Sir Wm. Mather and Sir J. Wolfe Barry, the respected chief in the world of textiles (then Mr. Macara) and others. The proceedings were well attended and even enthusiastic. If we recollect one feature more vividly than any other it is the speech in which Mr. Haldane, as he then was, extolled the German system in respect of its appreciation of the value of science and scientific principles, and in its method of dealing with the workman who would not

Much water has flowed under the bridges since that date; Governments have changed, and the turn of fortune's wheel has brought into power one in which the first President of the British Science Guild forms one of its most distinguished members - now Lord Haldane of Cloan - than whom, we supposed, few knew, or thought that they knew, the soul of Germany better. Within the intervening decade we have witnessed the immense development of Teutonic industries consequent largely upon their full appreciation of the value of scientific production and organisation and financial cooperation, assisted though, as everybody sees now, by unscrupulous machination. The British Science Guild is entitled to credit for all that it may have done to change the attitude of Governments, manufacturers, and the general public towards science, scientific education, and scientific principles, and Lord Haldane is equally entitled to our sympathy if to-day he has to deplore the fact that obsession with the manifold important duties devolving upon a Cabinet Minister, in a decade marked by very democratic tendencies, has prevented him from inducing the British nation to avail itself more thoroughly of the object lessons that he had been privileged to observe in Germany.

The second of the Mansion House Conferences, of which a report appears on another page, was not convened by the same Guild. Yet the speeches of 1915 had very much in common with those of 1905. The hall, the stage, the theme-were the same; there were other actors, but the need for a more general utilisation of science in industry was shown to be still one of the most urgent of all our needs, indeed the urgency of the question was emphasised by the added experience of these 10 years of German industrial advance. But the fact that we are now at death-grips with the people whose system Lord Haldane once extolled, should bring home to the national mind most forcibly the seriousness of the whole question in relation to our future trading abilities. We have ventured to hope that all the industrial lessons that we have been learning or re-learning since last July have persuaded Ministers, manufacturers, and others in authority, that this is no purely academic question, but one in which we are all vitally concerned. Yet, if we were to judge from the proceedings and attendance at this second conference, we should feel that we had yet a long way to go before the real facts had been properly brought home to the public mind. were permitted to listen to the reading of a chapter

Digitized by Google

from a book already published, which stated very convincingly once again how science has contributed to Germany's success in economical and competitive production. The audience was very small, but we should judge that those who were present knew the argument full well. There was a brief discussion, in which Sir Philip Magnus very reasonably asked what it was proposed to do to bring about the alteration that seems to be so essential, but it cannot be said that those who asked for bread got anything better than a stone. One of the most telling speeches was that in which Col. Cassel made an indictment of the Government itself—in which Lord Haldane sits upon the Woolsack—for advertising for chemists with high qualifications, for service at Woolwich, at two pounds no shillings and six pence per week! Of what avail is it to agitate for raising the scientific status if the Government itself values the services of scientifically-trained men in so niggardly a fashion, and when it excludes from the Board of British Dyes, Ltd., expert chemists of unquestionable eminence? The first President of the British Science Guild, if he still holds the views of his earlier years, should surely make his voice heard in the councils of his party in these momentous days. How can we expect to raise the status of science if we keep the monetary reward of the scientist below that of the artisan or labourer? The second conference seemed to agree that the matter was not one to tackle in a hurryno cut and dried scheme could be propounded. How far that attitude differs from the one adopted by the conference of 10 years earlier the few who were present on both occasions may be left to judge. Others who were present last month and care to turn to their ELECTRICAL REVIEW for November 3rd, 1905, may feel that there is much in common between the two reviews of the position and of the need for educating the race from top to bottom in regard to the value of scientific principles and their application in every department of life "to the problems which modern life presents in peace or war." Really from the standpoint of conference we do not appear to be any "forrader"—we are as conservative as ever in some things. The resolution passed last month stated that it was desirable, "in order to improve the working conditions in which British industry at present operates, that there should be closer co-operation between industry, science, and finance." In our opinion it does not require discussion to secure approval for that view from such an audience at this What is required is that something should be late date. done, otherwise we may see the end of this war, and talk on for another 10 years, perhaps losing ground all the while. Since the conference we have received a communication from the Institute of Industry and Science, which convened it, stating that something "will not be disclosed until the dinner which is to be given in about a month's time to leading industrialists, scientists, and bankers." We will endeavour to rest our souls in patience, waiting for something tangible. Publicity galore, advertisement and talk are not a very satisfying diet for hungry men.

THERE has been an uninterruptedly firm tone about the copper market for weeks past, and all the more cautious expressions of opinion which have been met with are now being thrown to the winds, as it becomes more and more probable that there is a big and concerted plan of manipulation at work to rig the market. American producers, stiffened by the contraband policy of the British Government, and backed as all the world knows by important German interests, are engaged in rushing up the price of their product, regardless of the fact that while they have been restraining output, thus keeping labour out of employment, they are also inveighing against the action of the Allied Powers in "stopping their trade." That it is sheer nonsense, does not appear a factor in the eyes of the German coppermongers, who are coining There is undoubtedly a large money while Europe bleeds. consumption of copper, and the full benefit of it falls into he coffers of the American copper producers, who, indeed,

are reaping a golden harvest, and who seem able to push up prices much higher still. Their argument that the British Government can afford to pay even £100 a ton is, no doubt, all right, for wars for national existence have to be fought out to the end, regardless of cost, and the German-Americans are no doubt quite wise in their generation in preferring to sit snugly at home in New York or Boston, and coin dollars, rather than put their manhood to the test in Flanders or in the desolation of West Russia. must be kept ever in mind that half-bred German interests are pretty powerful in America, and when these are linked up in an endeavour to rig the market in conjunction with what are frankly American manipulators, the result can only be higher prices. Output is being kept down as closely as may be to consumption, though the former has undoubtedly increased to a considerable extent lately. It is improbable in the extreme that the copper magnates will permit it to expand to a degree sufficient to permit of a decline in prices, and some of them are boasting now that the policy of small output and big profit has come to stay, as against big output and small profit. This can only foreshadow a period of manipulation, until possibly the American copper trade is again threatened with a Government inquiry based upon anti-trust lines. Something of this is being held over the heads of the American spelter industry now, and may have a restraining effect upon the cupidity of the leaders of the trade. The responsible head of the United States is, however, hardly the man to show stiffness of attitude in any matter requiring the display of virile qualities or statesman-ship. There is an additional factor, too, to be considered just now in the copper position, and that is, that the scarcity of vessels is becoming so great that it is a question whether shipments can be made from the United States to Europe on anything approaching the scale necessary to enable goods to be exported. For weeks past metals have been waiting shipment on the quay at New York, and they seem likely to wait there for weeks more. Shipping is not to be had, and this is the plain fact about the matter. Notices have already been given to certain large consumers here that it will not be possible to ship copper bought by them till July, and turn where one will, the same tale is told. Under these circumstances and in view of the manipulation at work, it is impossible to hold very bearish opinions as to America can put prices higher if it is considered desirable, and there is no doubt that the times are regarded as very auspicious for a campaign of squeezing Europe, such as has been initiated, and the early phases of which are now with us.

American
Trade
Activity.

WE have recently had occasion to call attention to the activity which is being displayed by the U.S. Government and American firms generally to take advant-

age of existing circumstances to improve their position in the world's markets. A further evidence of this activity has now come to our notice, this time with particular reference to the extension of trade with France. The American Consul-General in Paris, it appears, has arranged to publish a weekly bulletin of offers received from the United States giving names and addresses of the firms making the offers and the nature of the goods for sale. These bulletins will be distributed to all the trade organisations in Paris, by whom they will be affixed to notice boards, and they will also be given wide publicity in the monthly journals issued by these organisations. Accompanying each bulletin is an invitation to French firms interested in the offers to call at the office of the American Consul-General to examine letters, catalogues and It is hoped that by giving this wide publicity to the desire of American firms to increase their trade with France, satisfactory business connections will be made directly between French importers and American manufac-We cannot approve all the methods adopted by American Consuls in their work, but we can at least give them credit for their energy. This particular enterprise would appear to offer excellent opportunities for good, and now that British Consuls are displaying greater enthusiasm

than ever before, we may hope efforts to similar ends for British trade may be more numerous than they have hitherto been. Another evidence of American activity appears in a cable which has recently been received by the American Government from the Commercial Attache in Madrid, in which he states that the American Ambassador and he recently had an interview with the King of Spain, in which the latter expressed the opinion that the present moment offered an excellent opportunity for American interests, particularly in the mining and metallurgical industries.

As an off-set to the above, it is interesting to note that the American Consul at Buenos Ayres recently reported that a man of great experience in South America had told him that American firms were making a big mistake in refusing to send travellers to that market. He states that English firms have now five travellers to every three they had a year ago, soliciting orders for any kind of future delivery, as they are determined not to let the market slip away from them. He also says that even some German firms are keeping their South American men active, although no one can tell when they will be able to fill orders.

In our last issue we published a com-Preferential munication from Councillor William Rates. Smith, late chairman of the Ilkeston Electricity Committee, on the subject of tariffs for electrical energy, which calls for comment. It will be remembered that Mr. Smith resigned his position in order to champion the cause of a photographer who had been charged for electrical energy at lighting rates, although the photographic lamps of another member of his profession were supplied at the power rate; this case is not on all fours with that brought forward by Mr. H. Faraday Proctor some time ago, the question in the latter case being whether it was lawful to supply such apparatus at the power rate, whereas the former was apparently a true case of preferential charging, which is clearly contrary to the law.

The point to which we wish to call attention is the uncertainty which appears to prevail in some municipal quarters with regard to the powers of the supply authority. to formulate special tariffs, as exemplified in the first three questions submitted by the Ilkeston Corporation to the Local Government Board. The reply of the Board is, as Mr. Smith remarks, very significant, but it could have been anticipated by anyone who took the trouble to study the terms of the Electric Lighting Acts, which make it perfectly clear that, provided that the maximum charge specified in the authority's Special Act or Prov. Order is not exceeded, and provided that no undue preference as between consumers of the same class is exhibited, the authority is entirely at liberty to lay down a separate tariff for any and every class of consumer. We need only cite in support of this contention the fact that churches, offices, private residences, public-houses, factories, shops, basements, and other classes of consumer, have been and are differentially treated by various supply undertakers, although they all use the energy supplied for lighting. If energy is supplied for motive power at 1d. per unit, and if it is supplied for photographic purposes at 1d. per unit also, it is a mere coincidence or a matter of convenience that the two rates are identical—they really have nothing to do with one another. Parliament has not laid down any rule that power and lighting shall be charged for at different rates. nor has it specified that they shall be charged for at the same rate; the question is left quite open to electricity supply authorities-provided that no unfair preference is shown as between consumers of the same description. The Electric Lighting (Clauses) Act, 1899, Schedule, Sec. 33, states clearly that "the undertakers may make any agreement with a consumer as to the price to be charged

for energy, and the mode in which those charges are to be ascertained, and may charge accordingly. In a word, preferential rates are forbidden, but differential rates are permitted.

Patents in 1914.

The report of the Comptroller-General of Patents for 1914 naturally differs very materially from those of previous years.

The state of war has had various consequences upon both inventors and their inventions, and the all-absorbing subject of war has encouraged inventive ingenuity in military and naval matters, while our relations with other countries led to the passage of special Patent legislation. The statistics are, of course, affected, as the following figures for two years show:—

			1918.	1914.		
Patent application	18	•••	30,077	24,820		
Completed specific	cations		19 309	16,443		
Scaled specification	ns	•••	16,599	15,036		
Income		•••	£346,324	£322,829		
Expenditure	•••	•••	£191,423	£194,767		
Surplus			£151.901	£128 062		

In the course of the usual review of the trend of invention, it is stated that the electrical industry, as a whole, is very prominent, although there are few outstanding features that are considered to call for comment. Continued progress in automatic and semi-automatic telephone systems is noted, and attention has also been given to receiving arrangements for cable telegraphy, and to ionised gas relays for use in telephony and wireless receivers. The subject of locomotion in general still maintains its pre-eminence, and the flow of applications was equal to that of the previous year, until the outbreak of war, when a considerable fallingoff set in. Applications in connection with motor-vehicles and internal-combustion engines are still very numerous, but there is a notable falling-off in the total. Tractors for agricultural and military purposes, and signals for indicating to a following vehicle an intention to turn or stop, are mentioned as noteworthy features. The interest in visual signal-indicators for mines has been well maintained. There is a well maintained interest in railway signalling, without any marked departure from known types of apparatus.

Among the war features in the year's record is the stimulus given to aerial warfare and submarine mining. Methods for detecting submarines and torpedoes, and for protecting ships therefrom, are also specially noted. The disaster to the submarine A7 directed attention to the problem of locating wrecked submarines and signalling to,

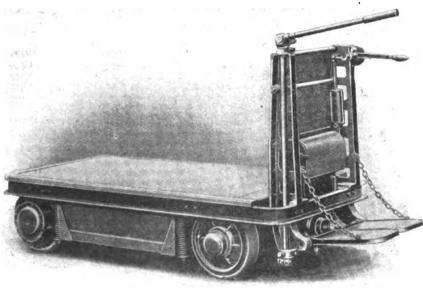

and rescuing, their occupants.

As to the future effects of the war upon invention, we cannot possibly foresee these, but it is certain that we cannot expect to avoid the consequences of wholesale carnage. Among the millions of lives that are being sacrificed are some of Europe's best. Potential genius, germs of inventive greatness, which might have benefited coming generations, are squandered at the bidding of Kultur-cum-Mili-The world generally is being robbed of its heritage. tarism. But there may be compensations as usual. Hundreds of thousands of men will never return to their former occupations, but may be compelled to subsist in calmer spheres where the inventive faculty may have a freer scope. The experiences of the period of war have turned thousands of minds in directions that they might never have followed in continued The new and vast constructive operations that will ensue when the destroyer's hand has been stayed will be sure to give a stimulus to innovation and invention, and the lessons learned from the applications of science in connection with German achievement may lead most countries to desire to spend larger sums upon research and investigation. It may be that, after accounts have been settled, German industrial concerns will have less money to devote in such directions, but though the financial stress and strain may be severe there will be a great unwillingness to cut down such items of expenditure, and inventive advance may contribute largely to the solving of coming problems, for is not necessity still the mother of invention?

### THE ELECTRIC VEHICLE.

### ELWELL-PARKER BATTERY TRUCKS.

We are glad to note that an up-to-date method of handling passengers' baggage, &c., on and about station platforms has recently been introduced by the London and North-Western Railway at Euston. Two Elwell-Parker battery trucks are now in use for conveying passengers' baggage and general platform freight. These were supplied by Mr. J. D. Gillespie, of the Railway Track Supply Co., who are sole agents for the Elwell-Parker Co. This class of truck is now being used in England for many purposes, chiefly amongst the railway companies. The Great Western, Midland, Lancs. and Yorks., and Great Central Railways

ELECTRIC BAGGAGE TRUCK SUPPLIED TO THE L. & N.W. RAILWAY CO.

have one or more Elwell-Parker trucks in use. At the Great Western Company's locomotive works at Swindon 14 Elwell-Parker trucks are employed for conveying works materials from one point to another; the trucks are easy to operate, and can be turned in a short radius. The cost of maintenance is exceedingly low, and the energy consumed very little. The L. & N.W. is the first English

railway company to employ these electric trucks generally for platform use, although other railways have experimented with them, and in every case the results have been successful. In the United States electric battery trucks are universally employed, the majority being of Elwell-Parker make.

The truck which we illustrate is of 2 tons carrying capacity; its special features are the automatic control, automatic braking and fourwheel steering. It is fitted with an Edison battery, carried in a spring suspended cradle arranged for easy removal of the battery for replacement, and a special motor operating at 24 volts pressure, and capable of running the loaded truck up a 15 per cent. gradient.

The motor and driving gear are enclosed in an aluminium dust-proof case; the motor pinion drives a differential on a countershaft, the pinions on the end of which engage with internal rim gears on the driving wheels.

The driver operates the steering lever with his right, and the controller handle with his left hand, while standing on a projecting platform. The latter is divided in halves, interlocked respectively with the control and brakes, so that when the driver gets off one side an automatic circuit-breaker in the main circuit opens, and when he leaves the other the brakes are applied. An upward movement of the controller handle causes forward motion, and a downward movement the reverse. Trucks are supplied with driving platforms at each end, the controls being interlocked. The speed of the truck loaded is 5 or 6 miles an hour; the turning radius of the outside wheels 12 ft. and it measures 12 ft. 5 in. × 3 ft. 9 in. over the body, weighing 2,780 lb. empty.

#### G.V. ELECTRIC MOTOR VANS.

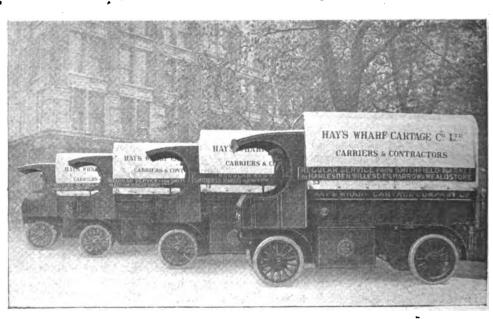

For some months Messrs. Hay's Wharf Cartage Co., Ltd., have been using 2-ton G.V. electric motor vans for delivering

meat from Smithfield Market to various firms in the London area and outlying districts, including Redhill, Kingston, Harrow, Enfield, Dartford, &c. It will be noticed that the vans, of which six are now in use, are regularly running on hilly country roads—the utility of the electric on well paved city streets is beyond question—and giving every satisfaction, so much so that a third repeat order has been given to the General Vehicle Co., who supplied the original vans, Messrs. Hay's Wharf Cartage Co. having satisfied themselves that, compared with horse vans, the saving to be effected in two years will be sufficient to pay for the first cost.

The vans frequently run 70 miles a day, as upon their return, after having run some 40 miles (the normal distance on one charge of the battery) they receive a boosting charge, and then run another 30 miles. The drivers, who were previously employed in driving horse vans, have quickly become accustomed to their new work.

The particular vehicles referred to have a sheet-covered van body with a driver's canopy, and are mounted on a standard G.V. chassis, fitted with rubber-tired wheels and roller bearings. There are two separated footoperated brakes.

A single totally-enclosed traction-type ball-bearing motor is fitted, capable of taking 300 per cent. overload for 20 minutes; this drives through Morse chain on to a diffe-

G.V. 2-TON ELECTRIC TRUCKS USED BY HAY'S WHARF CARTAGE CO.

rential countershaft and thence by roller chains to each road wheel.

A 44-cell Ironclad-Exide battery is carried below the chassis, and the controller is placed under the driver's seat and operated by a handle at the side; there are four forward speeds and two reverse speeds. A three-way running switch is provided having neutral, running and charging

positions; the driver can remove the handle in the neutral position, in which and the charging position the controller is inoperative.

An ampere-hour meter is fitted which automatically trips the circuit breaker when the battery is fully charged; the

meter also tells the driver the state of his battery.

We gather that the acceleration of these vehicles is excellent, and that on London roads they are running loaded at speeds of 15 to 16 miles an hour, although rated at only 12 miles an hour on the level.

#### INDUSTRY, SCIENCE AND FINANCE.

THE announcement that a Conference of the Leaders of Industry and Science would be held at the Mansion House on March 25th, to consider the mobilisation of industry and science and the working conditions in which British industry at present operates, and to suggest a new basis at the conclusion of the war may have raised hopes that this vitally important matter was at last to receive adequate treatment. Such was not the case. With all due deference to the positions and qualifications of those gentlemen who attended the Conference, we feel sure that they would be the last to maintain that the gathering was truly representative or worthy of the vast importance of the subject under discussion. The attendance may have been affected adversely by the fact that the Royal Society and the Chemical Society had meetings on the same afternoon, and it is peculiarly ironical that an Institute preaching efficient organisation should be the victim of clashing engagements.

One seeks in vain in the afternoon's proceedings for any vigorous and definite proposal of policy, and the resolution carried by the Conference "... that it is desirable, in order to improve the working conditions in which British industry at present operates, that there should be closer co-operation between Industry, Science, and Finance," is, at this late date, unu terably feeble. Of course it is desirable that there should be closer co-operation. That has been obvious for years past, and has formed the text of innumerable sensational but barren articles and treatises during the last eight months. The whole point is first to determine how such co-operation may be secured, and then to secure it. From this point of view, the Mansion House meeting was sterile. It is, as Sir Philip Magnus remarked, too much to expect a complete constructive policy to emerge from a single afternoon's discussion, but any institute essaying to increase co-operation between industry, science, and finance, by generalising on the subject, is simply wasting the time of its members. Precise schemes are needed, and, while we bear no ill-will against the Institute of Industry and Science, or any other body organised to deal with this important matter, we feel that the whole problem of co-operation is one demanding immediate attention by individual parties.

Individual manufacturers must realise that properly trained scientific men are good investments and, as such, are entitled to adequate remuneration and proper encouragement to invent and improve machinery and processes. Individual scientists must realise that their work must conform to the requirements and conditions of industrial practice or be handed over, at the earliest opportunity, to men able, by their training and experience, so to adapt and apply it. Individual bankers must realise that Messrs. A. and B.'s new works, new machine or new process is, subject to the judgment of a commercial scientist, whose mind does not live in a test-tube, a fit and proper security on which to advance capital for its development. It is no use talking about the matter as a general proposition. It is a subject for immediate action. Messrs. A. and B. can afford to pay salaries such as will bring them men with scientific qualifications and commercial and industrial experience fitting them to develop processes and plant on which Messrs. C., the bankers, can safely advance capital. But Messrs. A. and B. must not regard their scientific men as interesting freaks, commercially lunatic, to be snubbed as often as

possible and placed entirely under the control of a commercial board of directors.

With Sir Philip Magnus, we agree that our output of science, our standard of technical education and our industry and inventive genius are as great as those of the world in general and of Germany in particular. With Colonel C. E. Cassel, we agree that the present position of scientists in industrial concerns in this country is ineffective and degrading. We must imitate Germany to the extent of securing the best scientific advice obtainable and giving it proper weight and influence in our industrial councils. Faults in the past and present composition and working of individual firms must be fearlessly laid bare and ruthlessly uprooted.

The reason for these urgent words and drastic proposals is not far to seek. During the war, we have industrially a breathing space—so far as concerns German competition. Great and urgent as are our industrial problems in other directions, we must find time now to frame individuallysince it seems hopeless to expect any adequate general solution—the measures by which we are to conduct the coming industrial war. Once the sword is sheathed, the industrial ability and organisation of Germany will be directed to underselling in every market. The indemnity imposed by the Allies will compel great wage reductions in Germany, and the over-extended factories of that country will literally flood the world with cheap German goods. Nor shall we be immune from severe competition by our allies and by neutrals—chief among them America. To meet the unprecedented conditions which must surely arise and to avert what can only be lasting industrial ruin, we must cheapen production. As Lord Portsmouth took care to emphasise, this cannot be done in the United Kingdom by wage reductions. We shall have to increase our efficiency of production, which means utilising existing and new scientific methods to the greatest possible advantage—again a matter for immediate and sustained individual effort in individual cases. Organisation of sales and commercial methods in general is a closely allied but still distinct problem.

During the past century the development of science has exerted an ever-increasing influence on political economy, but, though we agree with Mr. J. Taylor Peddie that this has rendered unsound many of the theories formerly held by political economists and has practically given any and every industry to that country which prosecutes its development most scientifically, though we agree that the direct and reflex influences of inventions and improved methods and equipment are far-reaching, and have done more to further the progress of human development than any political measure, yet we feel that Mr. Peddie underrates the value of the assistance which can be given to science and industry, separately and conjoined, by judicious legislation and State finance. Extraordinary as the organisation of German firms has been, technologically and commercially, German industry could never have reached its present development without the diplomatic, legislative and financial assistance accorded to it by the German State. In these directions, we feel that it is up to our own Government to do many things which it has failed to do in the past, but the necessary machinery will take long to construct and bring up to speed. Meanwhile, the problem must be tackled and largely overcome by individual private effort. Until such effort has been made extensively and effectively, pressure can hardly be exerted on the Government, and definite schemes and policies can hardly be formulated with advantage by private associations.

Electrically-Driven Barges.—Our contemporary, the Motor Ship and Motor Boat, recently described a type of electrically propelled barge, of which about 100 are in service in one part of Germany, engaged in carrying bricks and limestone into Berlin. They are long shallow craft, built of steel, having a displacement of 250 tons and a draught under 5 ft. Their length is about 123 ft., beam 14 ft. 6 in., and depth 6 ft. A battery of 80 cells, with a capacity of 700 ampere-hours, each cell weighing 120 kg., is installed in a ventilated lead-lined chamber 10 ft. × 14 ft. × 5 ft., near the stern, and supplies energy to an 8-H.P. motor driving the propeller direct at speeds of 120 to 150 B.P.M. The speed of the barges is very low, not exceeding 3 miles an hour; they run trips in normal operation of about 70 miles, and are stated to have given satisfactory results.

#### THE CARDIFF ACCIDENT.

In our issue of March 26th last, p. 434, we referred briefly to the extraordinary accident which occurred on Sunday, March 21st, at the Roath electric power station of the Cardiff Corporation, and resulted in damage estimated at some £20,000, as well as the shutting down of the tramway service and dislocation of electricity supply in the city. We are now able to publish some views taken in the station after the accident, which will convey a better impression to our central station readers of the state of affairs then existing, than any amount of description. Some idea of the position, however, was conveyed in the report of Mr. Arthur Ellis, the city electrical engineer, at an emergency meeting of his Committee, held soon after the accident, when he is reported to have stated, amongst other things, that :-

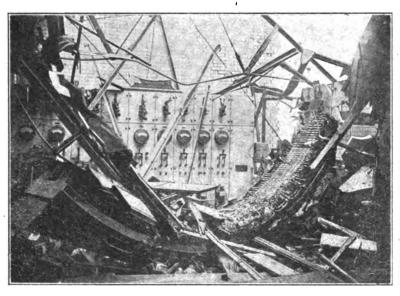

removed by that evening, after which the new circulating pipes would be put in and the new plant in the power station could then be put in commission.

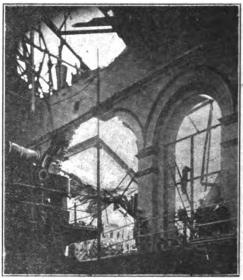

Whilst the accident itself was extraordinary, the escape from loss of life was more extraordinary still. One could see pieces of metal, weighing as much as 30 cwt., all over the place.

The cause of the accident was now quite unascertainable, and he did not think they would ever know the reason for it.

## AERIAL WIRE ROPEWAY FOR AUTOMATIC DISPOSAL OF ASHES.

Some years ago we published particulars of an aerial wire ropeway at the Neepsend electricity works of the Sheffield Corporation, installed by Messrs. R. White & Sons, of

SECTION OF STATOR WHICH FELL INTO SWITCHROOM. ACCIDENT AT CARDIFF POWER STATION.

THE DAMAGED ENGINE ROOM.

It will be remembered that the ropeway in this case

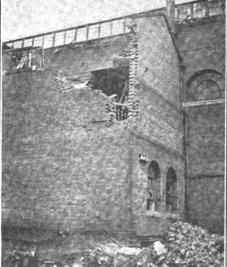

Widnes, for the automatic disposal of ashes from the boiler

The most urgent need of the moment was to give temporary cover to the machinery, which was now exposed to the weather.

The position was that one of the large en-gines had been entirely wrecked, and in his opinion it would not pay the Committee to re-erector re-construct it, because, nowadays, with a modern type of plant, they would prob ably get a turbine at considerably less coat than they would have to pay for the re-erection of the wrecked engine. He had never heard or known of anything of the kind happening in any elec-tric power station in the country before. He had no doubt in his mind that the engine accelerated to enormous speed, and the flywheel, of a deadweight of over 70 tons, with an electric generator of about the ame weight coupled to it, burst and simply shattered the end wall

shattered the end was and demolished most of the roof It also damaged the engine immediately opposite to it, but the damage that was not so extensive. The greatest difficulty had been activities to the row machinery. damaged the engine immediately opposite to it, but the damage to that was not so extensive. The greatest difficulty had been with the large 20-in, water pipes serving the new machinery. These had been broken, and the water rushing down the centre of the engine-room, together with the force of the bursting of the flywheel, had affected the foundations of the engine very seriously. Large masses of concrete had been loosened and broken up. It was found that the waterworks department had new pipes in stock. He was hoping that the concrete would have been removed in order to put the new pipes io, but there were many tons of solid concrete to be dealt with, and the task had been greater than anticipated. It was possible that it would be all

DAMAGED BUILDING CONTAINING H.T. SWITCHGEAR,

place, it automatically disposed of the ashes, and secondly, these ashes were used to fill up part of a ravine, and make it level with the railway line on the top side of the works, and so provide extra coal storage space, and room for extra railway sidings. This work has now been completed, and in order to find further tipping ground it has been necessary to erect a fresh ropeway across the railway line, and to tip the ashes on

some waste land on

the east side of the

railway.

This in-

served a dual pur-

pose. In the first

volved the raising of the ashes to a sufficient height to allow the ropeway to be carried well over the railway, and leave room for a protective bridge over the railway itself.

The level of the boiler floor at this point is about 50 ft. below the level of the line, and it was therefore necessary to provide two electric hoists with a total lifting height of 110 ft., allowing ample head room.

The ashes are loaded directly from the boiler furnaces into the tipping wagons, each wagon holding \(^a_4\) cb. yard, and

are then run by hand to the foot of the electric hoist. The man in charge turns an electric switch, and the wagon with its contents is at once raised to the top. At this point the wagon engages a bar fixed in such a way that the hoist not only stops automatically, but the wagon at the same time is automatically tipped into a storage hopper immediately below it, shown in the adjoining view. The man at the bottom then turns the switch again, and the empty wagon descends with the hoist. It will be noticed that the whole of this arrangement is automatic, and it is not necessary for the attendant to travel with the loaded wagon. The hoist is supplied in duplicate, and is driven by electric motors, with counterbalance weights in the usual way.

The hopper at the top is capable of holding 10 tons of these ashes, and when it is

full the man in charge proceeds to empty it by the use of the aerial ropeway. Fig. 2 shows one of the carrier boxes

-Side View of Loading, Driving and Tension Terminal of Ropeway, with Electric Hoists, Storage Hopper and Steel Staging.

FIG. 2.-LOADING A CARRIER BOX FROM THE STORAGE HOPPER.

which has just been loaded with ashes from

the hopper. It will be noticed in the views that the ropeway makes two vertical angles en route, and one horizontal angle. In order to comply with the railway company's requirements, it was necessary to run the line of the carrying rope horizontally, so as to keep the carriers, both loaded and empty, well within the sides of the protective bridge already mentioned. As soon as the ropeway leaves the railway it at once rises up a gradient of 1 in 3, until it arrives at the angle standard, which is 60 ft. high from the ground level, with an angle of 145°, as shown in figs. 3 and 4, in order to provide plenty of tipping height. The carriers, whether loaded or empty, pass through this angle station quite automatically, both on the forward and return journey.

From

carriers proceed directly over the tipping ground, where they are discharged automatically in the manner shown in fig. 3. Proceeding onwards, they are conveyed to the far end of the line, where there is an automatic return

Fig. 3.—RETURN TERMINAL OF ROPEWAY, AND CARRIER DISCHARGING ASHES.

terminal fixed at a total height of 50 ft. above the ground level, as shown in fig. 8.

The ropeway is erected on the side of a ravine, and in addition to the very high tipping space provided by the standards themselves, there is room for a very large quantity of material, due to the peculiar formation of the ground at this point, and it is estimated that the ropeway in its present position, although only 600 ft. long overall, will provide tipping space for about 53,000 cb. yards of ashes. means of Messrs. White's special arrangement of dummy standards this space can eventually be increased to about 200,000 cb. yards.

It is understood of course, that the tipping, as in

the previous installation, is done entirely automatically, as is clearly shown in fig. 3, and the carriers not only go round the return terautomatically, minal but also through the angle station, so that as a matter of fact the carriers are not touched by hand from the time they leave the loading berth until they arrive there again on the opposite side of the ropeway, where they are automatically released from the hauling rope and stand on the fixed run rail ready to load again.

The ropeway is designed for carrying 10 tons per hour, but this can be increased if necessary by merely adding extra buckets. It is driven by a motor of 6 B.H.P., of the protected type, fed with two-phase alternating current at 200 volts, 50 periods, and provided with an auto-transformer starter. The electric hoists are driven by means of similar electric motors of

12 B.H.P. each, with wound rotors, and controllers of the reversible type.

Messrs. Gilbert Heathcote & Co., of London, provided the bridge over the railway; the whole of the remainder of the installation, including the electric hoists, was provided by Messrs. R. White & Sons, of Widnes.

The installation is a very interesting piece of work, and we congratulate Mr. Fedden, manager of the electricity department, on the satisfactory results attained.

### LEGAL.

THE RETURN OF ELECTRICAL GOODS.

In the City of London Court on Friday, March 26th, before Mr. Registrar Wild, a claim was made by Otto Bohndel (sole proprietor of Schoen Bros.), 29, Cock Lane, against the Wirthy Incandescent Light Co., electricians, 200, Portobello Road, Notting Hill, for the balance of account for electrical goods supplied in the way of trade.

The PLAINTIFFS' representative said that the claim arose from the fact that the defendants had returned goods which the plain-tiffs could not accept. The goods were delivered in June, 1912, and the defendants returned them in July, 1914. Of course the plaintiffs could not accept back goods which had been kept for over two years.

The DEFENDANT said the statement was not true. The arrange The DEFENDANT said the statement was not true. The arrangement made with the plaintiffe' traveller was that all faulty goods should be returned, and that was what had been returned. As, however, the defendants had stopped dealing with the plaintiffs, they had refused to change the last lot of goods.

The REGISTRAR: It is said that the goods returned were delivered in 1912.

delivered in 1912.

The Defendant: No; they were not.

The Plaintiffs' Representative: I can prove it.

The Defendant said there was one line, amounting to 1s. 7½d., delivered in 1912. The rest of the goods returned were delivered

in January, 1914, and were returned in July.

The Plaintiffs' representative said their agreement was that no goods could be returned after six months.

The Defendant said the plaintiffs had always changed goods previously, and had never stipulated that it should be done in eix months.

The Registrar intimated that if the defendants ordered goods of the plaintiffs upon ordinary sale or return terms, kept the goods for six months, and then returned them, in his (the Registrar's) opinion, that was a great deal too long to keep them, unless it was shown that there was a contract between the parties to that effect, or that it was well known in the trade that goods could be kept for six or seven months before returning them.

The Defendant said he could only prove his arrangement by pre-

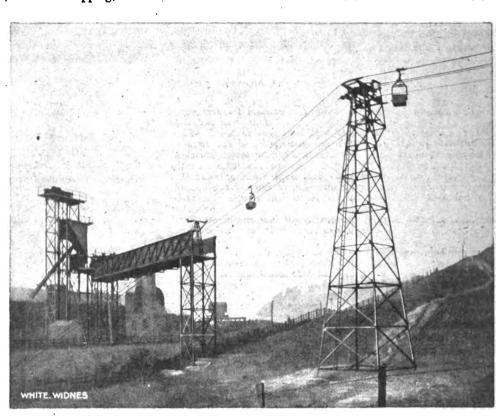

FIG. 4.—BRIDGE OVER RAILWAY, AND AUTOMATIC ANGLE STANDARD.

vious transactions, and he had not brought the necessary papers with him to do that.

The Registrar suggested that the defendants point might be brought out by questions asked of the plaintiffs witness, but the plaintiffs' representative said they would not exchange any goods after six months.

Continuing, the Witness said when the defendant returned the goods plaintiffs went through them carefully and exchanged part of them. Others they could not accept, having been too long delivered.

The Defendant said the arrangement made with the plaintiffs' traveller was that they could exchange batteries and lamps after six months.

Plaintiffs' representative said no such agreement was ever made

with the defendants. They could not do it.

The Defendant stated that his dealings with the plaintiffs were through their traveller, who had said the firm was very fair in its dealings.

its dealings.

In answer to the Registrar, it was stated that the goods in question were of German make, and the Plaintiffe' representative remarked "about the best ever supplied in the trade."

The Defendant: We thought we could not get a British article better than the German. We did not know it until now.

The Registrar pointed out that a part of the case that seemed to strike him was that some of the goods might have become faulty while in the defendant's possession.

The Defendant: That was the reason for the guarantee being given. Further, he said he had kept batteries in stock for 12 months and the plaintiffs had exchanged them and had said nothing against it until now.

nothing against it until now.

The Registrar said if the defendant could prove that the plaintiffs had accepted back goods under circumstances such as he alleged, there might be something in his case. It was denied by the plaintiffs, and the defendant's contention seemed unreasonable to him (the Registrar).

The Defendant, in answer to questions by the Registrar, said there was nothing to prevent him testing batteries. He did not send back one or two batteries at a time, but at the suggestion of the traveller had kept them until he had a number of faulty articles to return.

The Registrar thought there was something in the defendant's suggestion as to keeping some of the goods over time, while wait-

ing to return others in time, and ordered the case to be adjourned for the plaintiffs' traveller to attend. The Defendant should also bring his documents to prove that he had returned goods to the plaintiffs as he alleged.

On Tuesday, March 30th, the defendant produced two credit notes in respect of goods which he had returned and which he said had been kept as long as the returned goods over which the

dispute now arose.

The REGISTRAR said he should require to see the invoices under which the goods, in respect of which the oredit notes were given, were supplied. Without seeing such documents he (the Registrar) could not judge whether the goods had been returned within a reasonable time or not.

The Defendant said he did not think about bringing the invoices

within him.

The Registrar said he saw that the credit notes were dated September 13th, 1912, and February, 1913, but the goods might have been invoiced the day before. The defendant wanted to prove that notwithstanding that a period of six months had elapsed it was a custom in the trade in his dealings with the plaintiff that he result accept the return of goods after such a period. The would accept the return of goods after such a period. The adjournment had been given for the defendant to prove his assertion. He (the Registrar) was afraid he could not help the defendant.

The Defendant said he thought the credit notes would be

sufficient for his purpose.

The Registrar said the credit notes were only evidence that goods were returned upon certain dates, but they did not state how long the goods had been kept, and the plaintiffs complained that the defendants had kept the goods far too long.

The Defendant said he had kept back some batteries which were faulty, at the express request of the plaintiffs' traveller.

The plaintiffs' traveller, Ames, denied that he had requested the defendant to keep back batteries (dry cells); they were to be sent

defendant to keep back batteries (dry cells); they were to be sent back immediately.

The Defendant said that that was a perfect lie.

The Registrar said that the defendant did not give him an opportunity of judging whether there had been such a customary dealing as he alleged. Therefore the case came back to the question whether it was reasonable for the defendant to have kept the goods as long as he had. The goods now in question had been kept at least seven months. The defendant had not proved his custom, and the plaintiff would have independ for the amount. custom, and the plaintiff would have judgment for the amount claimed, without costs.

#### THE PRIZE COURT.-SEIZURE OF ELECTRICAL FANS.

In the Prize Court on March 30th the President, Sir Samuel Evans, had before him a suit by the Crown asking for the condemation as enemy property of five cases of electric fane, seized on board the P. & O. steamship Paona, in London on October 17th. The goods were claimed by Isaria, Ltd., a company duly incorporated in England.

MR. J. B. ASPINALL, for the Crown, said that the fans were sent to Germany at some time before the outbreak of war by Isaria Zahlerwerke, of Munich. The outer wooden case in which the goods were packed bore labels printed in Germany, and also had the words "made in Germany" stencilled upon them, and each of the fans was wrapped in paper bearing printed German labels. They were forwarded to Australia by the steamship Rheinland, but were afterwards sent back to this country to Isaria, Ltd., a com-pany duly incorporated in England.

pany duly incorporated in England.

The PRESIDENT: When did they reach Australia?

MB. ASPINALL: Before the outbreak of war. They were sent back to this country on the ss. Poona, consigned by Messrs.

Lascelles, Parrington & Brasche, of Melbourne, "to order," London

The PRESIDENT: How did the firm in Melbourne get possession

of the goods?

ME. ASPINALL: They were hauded over to them by one Brandl, who is alleged to be the Australian traveller of the English company, but who I shall sak your Lordship to say was the Australian traveller of the German company. I submit that these goods were so tinged with German interest that they ought to be condemned. so tanged with derman interest that they ought to be condemned. The contention on the other side is that the goods are the property of the English registered company. Counsel quoted the following passage from the judgment of his Lordship in case of "The Tommi and Rothersand," with reference to the question of an English company consisting entirely of aliens. "These technicalities have not been allowed to bind decisions in the Prize Court. They have been treated rather as gossamer to be brushed aside, and the Prize Court rather regards the essential qualities of any transaction and tries to arrive at the realities of the case. . . . It no doubt is the case that a company registered in this country under the Companies' Acts is a separate entity, and such a company can own a ship. Whether a company consisting entirely of aliens can own a surjection ship is a question which probably has never arisen, and has never, therefore, been decided. I am not sitting here dealing with maritime law, and, therefore, I am not called upon to decide that question, but I do not want it to be assumed that the Prize Court could not say, looking at the realities of this thing, that even if the transfer has been completed, and if the shareholders in the British company became the purchasers, this vessel ought to be regarded as a German ship."

The PRESIDENT: That was before the decision of the Court of

Appeal in the Continental Tire and Rubber Co.'s case.

MR. ASPINALL agreed. In that case it was held, Lord Justice
Buckley dissenting, that an action of debt was maintainable by an English company of which all the directors and shareholders were alien enemies. Lord Justice Buckley's dissenting judgment, however, was of very great force and strength, and Lord Lindley, in a letter to the Times, agreed with him.

MR. ASPINALL called attention to an affidavit by Mr. Frank Morton, manager of Isaria, Ltd., of 208, Tower Bridge Road, from which it appeared that the company were merchants, and dealt in electrical appliances, including electrical fans. The great majority of the shares were held by the German company. Four directors of the shares were held by the German company. Four directors of that company and another person, all resident in Germany, held one share each, while another share was held by a Frenchman.

In reply to the President,

MR. ASPINALL said that looking at the reality of the transaction MR. ASPINALL said that looking at the reality of the transaction his case was that the goods were probably the property of the German company. But even if they were not, but were the property of the English company, then he contended for the purpose of prize, that that company was so German that if the goods belonged to them they ought still to be condemned. He asked his Lordship to follow up what he said in "The Tommi and Rothersand case," and look at the "realities of the thing." He submitted that apart from the decision of the Court of Appeal his Lordship sitting in prize with a discretion and with an ability to Lordship sitting in prize with a discretion and with an ability to look through the transaction, would do justice to the British Crown. He invited the President to consider very seriously whether looking through the fog of the class of affidavit put forward in this case, he could not see the light and the real truth of the matter, and to use his Lordship's own expression brush aside

THE PRESIDENT: Perhaps that expression was a little too

strong.

MR. ASPINALL: I think it was an expression extremely apt for

the purpose of that case, and very suitable for my argument.

MR. BLKIN, for the claimants, said his submission was that where the goods were shipped and seized in a British ship trading between two British ports, the onus was on the Crown to prove that the goods were of an enemy character.

The President : No.

MB. ELKIN said that then he submitted that the goods were clearly the property of the English company, and as such were not confiscable. The transaction was a simple one. The goods were contiscable. The transaction was a simple one. The goods were ordered from the Munich company by the British company, and were sent direct to Brandl, the British company's Australian traveller, and he handed them over to the British company's Australian agents, Mesers. Lascelles, Parrington & Brasche, on sale or return terms. The goods proved not to be suitable for the Australian market, and the agents shipped them back to London. At the time of seizure they were the property of the English company. company.

MR. FRANK MORTON, the English company's manager since August 3rd, gave evidence to the effect that the goods were bought outright by the English company from the German company, and had

been paid for by running account.

been paid for by running account.

In a letter which Messrs, Lascelles, Parrington & Brasche wrote in September, when forwarding the bill of lading in respect of the goods to the English company, this passage occurred:—"There has been some delay in connection with the matter owing to the war, as it was Mr. Brandl's intention to attend to the business, but he has been naturally very unsettled, and as the bill of lading is no good to us, the best thing to do is to let you have it, and trust that you will be able to obtain possession of the goods."

The hearing was adjourned till Tuesday. April 13th, for further

The hearing was adjourned till Tuesday, April 13th, for further

evidence.

#### COSTELLOE r. UNIVERSAL RADIO SYNDICATE, LTD.

AT Listowel (County Kerry) Quarter Sessions last week, before County Court Judge Dromgoole, John Costelloe, formerly an employé at the wireless telegraph station at Ballybunnion, County Cork, sued the Universal Radio Syndicate, Ltd., in liquidation, for damages for injuries sustained whilst in their employment.

The Prayer in his evidence stated that for about 10 months

The PLAINTIFF, in his evidence, stated that for about 10 months he had been employed at Ballybunnion wireless station, owned by the syndicate. On January 18th last he received notification from the manager to the effect that his services would not be required after Saturday, January 23rd. In accordance with the usual custom, he was paid, with the other employés, about noon on January 23rd, but was not to leave work until 5 o'clock that evenfour other employes went, at about 2.30 o'clock, and together with four other employes went, at about 2.30 o'clock, up the pole or tower of the wireless station, which is about 490 ft. high. They went up from the inside for the purpose of fixing steps. Their directions were that whenever the weather permitted they were the tower and fix out the steps. The morning of January ascend the tower and fix on the steps. The morning of January 23rd last had been very wild, and when the weather cleared up at 2.30 o'clock, they ascended in accordance with the instructions received. At about 4.15 o'clock, after fixing on about 18 steps, they decided to go down again as the evening was getting dark, and when at a distance of about 40 ft. from the ground plaintiff lost his hold and fell to the ground—a concrete foundation. He received injuries to the head, neck, legs and sides, and, as a result, was under the treatment of Dr. J. Costello for about eight or ten days. Although no bones were broken plaintiff still felt very sore, and was unable to work.

The evidence was corroborated by the other men who were working with the plaintiff.

MR. C. T. ELWELL, manager for the syndicate for the defence, said the men had no authority to ascend the tower on that

His HONOUR held that the plaintiff was in the employment of the syndicate at the time of the accident, and granted plaintiff a decree for £5 and costs,

HERBERT MORRIS, LTD., v. SAXELBY.

THE Court of Appeal, composed of the Master of the Bolls, Lord Justice Phillimore, and Mr. Justice Joyce, on March 31st, delivered judgment in this case upon the plaintiffs' appeal from a judgment

judgment in this case upon the plantine spices from a judgment of Mr. Justice Sargant.

The proceedings in the lower Courts have already been fully reported in our pages.

The MASTER OF THE ROLLS held that the covenant was unreasonable and was an unusual one in the engineering trade. He could not, he said, think it was reasonable to require the defendant to put aside all the skill and experience he had acquired and to practically begin life afresh. There was during 10 years, and to practically begin life afresh. There was no suggestion that the defendant had been guilty of any breach of confidence or that he had disclosed, or threatened to disclose, any secrets of the plaintiff company. He thought the decision of Mr.

Justice Sargant was correct.

LORD JUSTICE PHILLIMORE discented, being of opinion that the covenant in the modified form, to which the plaintiffs agreed, was not too wide. He thought, therefore, that the appeal ought to be

allowed.

MR. JUSTICK JOYCE agreed with the judgment of the Master of the Rolls, and the appeal, therefore, by the majority of the Court, was dismissed, with costs.

#### LIGHTING SUMMONSES.

At the Manchester Police Court on Thursday last week the Stipendiary Magistrate fined two shopkeepers trading in a main thoroughfare £1 apiece for having too brilliant a light in their shop windows after having being cautioned. These were stated to be the first cases in Manchester under the Defence of the Realm Act lighting restriction order.

### ELECTRICAL SUPPLY TRADE IN SOUTH AMERICA.

THE following are extracts from certain reports which have been received by the American Government from its Consular representatives in South America as a result of the general inquiry referred to in a leaderette in a recent issue of the ELECTRICAL REVIEW, as having been made in oversea countries with a view to the possible expansion of American trade in electrical goods; the reports are not being published in full, but are being reserved for inspection by American manufacturers

inspection by American manufacturers.

ARGENTINA (BOSABIO).—Argentina offers a growing market for electrical supplies of all kinds. The total imports of such goods increased steadily from about £643,000 in 1908 to about £1,951,000 in 1913; and while the figures for 1914 will undoubtedly show a falling off, this can be ascribed to temporary causes—financial depression, in the first place, and the interruption of trade with Continental Europe.

Electricity is extensively used in all the leading centres of population and is gradually entering the smaller country towns, many of which are already electrically lighted. The industrial census of 1910 showed that in that year, or somewhat earlier, 21,790 electrical horse-power were used in Argentine industrial establishments, and the census taken last June will undoubtedly reveal a electrical horse-power were used in Argentine industrial establishments, and the census taken last June will undoubtedly reveal a great increase in this direction. Opportunities for the utilization of water power in the Andes and other mountain regions, as well as the current of the Uruguay River between Hervidero and Santo Tome, will give an additional impulse to the use of electricity for light and power. It is safe to say that the demand for electrical supplies will increase steadily in Argentina; on the other hand, it will be a long time before foreign firms will have to meet serious home competition in this field.

Official statistics of imports give to Germany the leading posi-

home competition in this field.

Official statistics of imports give to Germany the leading position for practically all kinds of electrical supplies. The United Kingdom is the chief source of a few lines, particularly certain grades of wire, commutators, vulcanised fibre, telephone and telegraph supplies (imported largely by British companies operating in Argentims), batteries, &c. The United States led in 1912 (the latest year for which detailed figures are available) in only two lines, namely, small motors (called "motorcitos"), of the type used for driving electric fans, &c., and wall sockets.

for driving electric fans, &c., and wall sockets.

The failure of American manufacturers to obtain a larger share of the trade in electrical goods is generally attributed to the fact that German products are lower in price and German firms more liberal in the matter of terms. Another factor is undoubtedly to be found in the absence of large consumers of electrical supplies operating with American capital and interested in the extension of operating with American capital and interested in the extension of American trade. European concerns controlling Argentine railways, tramways, power plants, electric-light companies, telephones, &c., are in some instances directly interested in the manufacture and sale of electrical supplies. The importance of this will be seen when it is stated that in 1912 electrical supplies, valued at about £225,000, were entered free of duty; that is, by railways and other public utilities enjoying the privilege of free entry.

Several leading European and American manufacturers of electrical materials are represented at Buenos Avres either by agents or

trical materials are represented at Buenos Ayres either by agents or by branches. The present tendency appears to be to establish branches. As regards Rosario, one of the large German factories has a branch here, and an electrical concern with factories in several countries is represented by the Rosario branch of its Buenos Ayres agents. ():her concerns represented at Buenos Ayres

are in close touch with the Rosario market, most of them selling to local dealers without distinction,

Some of the large general importers of hardware and machinery at Rosario maintain an electrical section, import electrical supplies, and install lighting systems, small power plants, &c. There does not seem to be much inclination on the part of these large hardware and machinery jobbers to extend this branch of their business; in fact, it appears from information obtained recently that some of these firms intend to give up their electrical sections. as the active competition of a host of small electricians, largely Italian, has reduced profits on electrical work to a minimum. The tendency is rather for the leading manufacturers to establish branches at Buenos Ayres, which will presumably be followed later by supplies at Rosario, which deal direct with the electricians and dealers. This does not, of course, mean that some of the Rosario inhere importing direct on hunting from Branches. jobbers, importing direct or buying from Buenos Ayres branches, do not continue to do an important business. It is evident that with leading manufacturers represented at Buenos Ayres it is difficult for firms, without good connections in Argentins, to get any important share of the trade. As already stated, difference in price and readiness to grant credit have thus far given German price and resolness to grant credit have thus far given German manufacturers a considerable advantage. As long as the war lasts Germany will experience difficulty in supplying the local market, but American manufacturers are reminded that the United Kingdom already does a much larger business in electrical supplies with Argentina than does the United States, and that Italy is only a short distance behind. The Sociedad de Electricidad de Rossrio (light and power plant), in an effort to increase the consumption of current at Bosario, particularly during those hours when consumption is ordinarily ticularly during those hours when consumption is ordinarily smallest, has rented a large store on one of the principal business streets, and has there installed electric fans, drying apparatus, toasters, irons, table and cooking utensils, stoves, motors for sewing machines, &c. While the company does not seek to sell apparatus or appliances, it may eventually carry a small stock of articles that local firms do not handle. When business picks up again the activities of the Sociedad de Electricidad may be expected to lead to an increased demand for electric appliances and supplies at Rosario.

BRAZIL (PERNAMBUCO).—Considering its population of some 250,000, Pernambuco's present demand for electrical supplies is small, but as soon as the plant now nearing completion is ready to furnish current to the city—which will be about May 1st—an opportunity will be presented for the introduction of electrical materials of all kinds. Manufacturers and exporters of such goods materials of all kinds. Manufacturers and exporters of such goods are advised to begin immediately to study the conditions on the market and to make satisfactory business connections with a view to extending their trade later in this district, inasmuch as Pernambuco is the distributing point for many small cities, some of which already have electric lighting and power stations, and others are now arranging for the installation of such plants. Olinda, a suburb of Parnambuco but having a separate municipal Government. suburb of Pernambuco, but having a separate municipal Government, has its own lighting plant. It has been reported that a concession for an electric lighting and power plant at Goganna, a city of about 15,000 inhabitants, some 50 miles north of Pernambuco, has been granted to a Brazilian company, which contemped to the second of the contemped to the second of the contemped to the second of the contemped to the contemped to the contemped to the contemped to the contemped to the contemped to the contemped to the contemped to the contemped to the contemped to the contemped to the contemped to the contemped to the contemped to the contemped to the contemped to the contemped to the contemped to the contemped to the contemped to the contemped to the contemped to the contemped to the contemped to the contemped to the contemped to the contemped to the contemped to the contemped to the contemped to the contemped to the contemped to the contemped to the contemped to the contemped to the contemped to the contemped to the contemped to the contemped to the contemped to the contemped to the contemped to the contemped to the contemped to the contemped to the contemped to the contemped to the contemped to the contemped to the contemped to the contemped to the contemped to the contemped to the contemped to the contemped to the contemped to the contemped to the contemped to the contemped to the contemped to the contemped to the contemped to the contemped to the contemped to the contemped to the contemped to the contemped to the contemped to the contemped to the contemped to the contemped to the contemped to the contemped to the contemped to the contemped to the contemped to the contemped to the contemped to the contemped to the contemped to the contemped to the contemped to the contemped to the contemped to the contemped to the contemped to the contemped to the contemped to the contemped to the contemped to the contemped to the contemped to the contemped to the contemped to the contemped to the contemped to the contemped to the plates erecting a 200-kw. station and also a 100-kw. anxiliary hydroelectric plant. Maccio, the capital of the adjoining state of Alagoas, Parahyba, the capital of the State of the same name north of Pernambuco, and Natal, the capital of Rio Grand do Norte, have electric lighting and street railway systems.

COLUMBIA (CARTAGENA).-Electric stoves have not come COLUMBIA (CARTAGENA).—Electric stoves have not come into use as yet in the Cartagena Consular district. The old-fashioned Spanish clay stove, burning charcoal, still holds first place. Electric stoves would prove far too expensive for the vast majority of families in this section. Further, the electric light and power company furnishes current during the night only; a uniform charge of \$1.50 per month for one 16-c.P. light is made. There is no meter system. There has been some discussion regarding the installation of a larger and more modern plant, but no definite steps have been taken, and it is probable that nothing can be done until commercial conditions improve considerably. considerably.

VENEZUELA (MARACAIBO).—Electricity for lighting purposes is now in general use throughout the larger towns of the Maracaibo district, but the fact that power is supplied only at night effectively eliminates a trade in electrical household articles, such as irons, stoves, vacuum cleauers, and washers. Beauty in lighting is not striven for; there is scarcely any attempt to conceal the wiring, and the call for electroliers is slight. Electrical signs and advertisements are unknown here. Wire and wiring materials are imported direct by the companies supplying the power; hardware firms handle a small number of portable lights, electroliers, telephones, &c.

Electrical Trades Benevolent Institution.annual general meeting that is, as already announced, to be held at the Institution of Electrical Engineers, Victoria Embankment, W.C., on Monday, April 19th, at 6.30 p.m., the report and accounts for 1914 will be submitted, and the following members of the Committee of Management, who retire by rotation, will be eligible for re-election:—Messrs. E. J. Clark, Guy Burney, H. Bevis, H. H. Berry, Lt.-Col. H. M. Lesf, Lord Vaux of Harrowden, F. J. Walker, R. J. Wallis-Jones, and S. D. White.

#### WAR ITEMS.

The present war will no doubt be the Trade with Italy .but it will only be temporary unless United Kingdom firms awake to the fact that more practical and up-to-date methods—must be adopted for cultivating the Italian market. Since the last years of the nineteenth century, German trade with Italy last years of the nineteenth century, German trade with Italy has increased proportionally by leaps and bounds. This is the result of perseverance and adaptation, not of chance, and British firms interested in the Italian market should bear in mind the following points to which German export commerce owes a great deal of its success, viz.:—

Representation.—The German trader cultivates his market either by personal visits or else by means of well-trained commercial travellers speaking fluent Italian, whereby personal contact with customers is established. On the other hand many British traders conduct their business in Italy by correspondence with agents they have never seen.

Quotations.—The German trader invariably quotes in Italian currency or in French gold, and in metric weights and measures, preparing his catalogues and price-lists ac-

Quotations.—The German trader invariably quotes in Italian currency or in French gold, and in metric weights and measures, preparing his catalogues and price-lists accordingly, whereas his British competitor usually seriously handicaps himself by quoting in £ s. d. and in British weights and measures, so that calculation and comparison are extremely difficult for the Italian buyer.

Delivery.—Most German traders will deliver "franco domicile," thus saving customers the trouble of calculating freight, duty, carriage, etc. Or his quotations are at least given c.i.f. port of disembarkation, whereas British offers are still often merely made f.o.b. British port.

Credit.—Thanks to his system of personal contact with customers, the German trader is in a position to judge what credit may safely be granted, and is thus generally able to give much easier terms of payment than his British competitor. In spite of the long credits often conceded, it is said that the Germans very seldom made bad debts.

Trade Grouping.—The system in vogue in Germany of grouping several large firms together to work in conjunction, no doubt had the effect of assisting German penetration. If an extensive and complicated industrial plant is required, it is difficult to find a British firm to supply all the different parts, and still more difficult to find that the various units combine in such a way as to make a perfect whole. Most British firms are specialists, and in order to fayour British

parts, and still more difficult to find that the various units combine in such a way as to make a perfect whole. Most British firms are specialists, and in order to favour British contractors, it is necessary to sub-divide contracts, giving rise to difficulties, besides the trouble the customer has in treating with several contractors.

The majority of solid people in Italy would prefer to do business with the United Kingdom if only things were made easier for them. The British manufacturer should therefore be much more painstaking as regards the Italian market, and advantage should be immediately taken of the present conjuncture to establish a firm footing, for otherwise it is to be feared that, after the war, Germany will rapidly make conjuncture to establish a firm footing, for otherwise it is to be feared that, after the war, Germany will rapidly make good the ground she now seems to be losing. Discouragement should not be felt if profitable business does not immediately ensue; close quotations, reasonable credit terms, perseverance and adaptability, will be required, and with regard to the language, if it is not possible to use Italian, French will be found very useful. Representatives of British firms travelling Italy will be afforded assistance at the various offices of this Chamber, especially with regard to suitable. ous offices of this Chamber, especially with regard to suitable agents, likely buyers, interpreters, etc. The Chamber is prepared to receive and exhibit in its Genoa offices, free of charge, any small samples or catalogues of British merchandise that may be sent to it; catalogues should be sent by book-post, small samples as "samples, no value," but registered.—"Bulletin of the British Chamber of Commerce for Italy."

Science in Industry.—Sir William Lever, presiding recently at the annual meeting of the London Commercial Travellers' Association, said that they heard a good deal about capturing German trade. As reported in the "Financial Times," Sir William Lever said that when they talked in a narrow way of antagonism with the entire solutions and their country, they must not let the war observe their view. talked in a narrow way of antagonism with the enemies of their country they must not let the war obscure their view of the fact that countries were dependent upon each other in regard to commerce. We had in this country the finest material and all the attributes which made for leadership and for maintaining the initiative, but we had allowed them to slip behind. The technical training which our youths required to fit them for the highest positions in the scientific conduct of business had been neglected. If we were to capture German trade, it could only be done on the besie of the ture German trade, it could only be done on the basis of the application of greater scientific training in general. They must have a better article to show. If we concentrated on more scientific attainments and found our business outlook enlarged, that would be one of the many useful lessons of this war.

merce for Italy.

Melbourne Contract.—According to a report in the "Melbourne Age," for February 10th, at a meeting of the City Council Coun. Cabena, chairman of the Electric Supply City Council Coun. Cabena, chairman of the Electric Supply Committee, submitted a report on the tenders which had been received for the supply of a 5,000 kw. turbo alternator for the city power house. He stated that about sixty tenders had been received, the most favourable being that from the British Westinghouse Electrical and Manufacturing Co., of £15,111 for the plant, and £1,015 for spare parts. In accordance with a previous resolution of the Council, the Finance Committee had asked for a statement from the company as to whether any German or Austrian material, manufacture, or capital, would be employed in supplying the plant. The Committee had received a sworn affidavit from the Melbourne manager of the firm stating that out of 2,432 shareholders in the company, representing a capital of 21,150,000, there were only five persons whose names appeared to be German or Austrian, and these only held shares to the amount of a little over £2,000. "I believe," said Coun. Cabena, "that it would be practically impossible to get any large concern that is nearer to being an all-British Coun. Cabena, "that it would be practically impossible to get any large concern that is nearer to being an all-British company." Coun. Davey said he agreed with the remark of Coun. Cabena that it was very difficult to get any large company without a small amount of German capital. But were they going to discriminate between a small amount and a large amount? He did not think the case was any worse or better than the case of Siemens Brothers. As they did not exclude consideration of Siemens Brothers' tender, he certainly supported the recommendation, which was he certainly supported the recommendation, unanimously adopted. which was

Sydney Contracts.—It is reported in the "Sydney Morning Herald" that on February 9th, at the City Council meeting, a letter was read from the British Trade Commissioner (Mr. G. T. Milne) pointing out that, if the recommendation of the Works Committee, that no contract be entered into with a British firm unless all the shareholders were British, was carried, the interests of a number of bonâ-fide British concerns would be gravely prejudiced. Under the conditions of modern industrial finance, and owing to the international character of Stock Exchange operations, some of the shares of a company strictly British in character might be held by foreigners without in any degree modifying the company's essential character. Its capital might be wholly employed in the United Kingdom in the manufacture of goods wholly made by British workmen, and so long as the majority of the shares were held by British subjects the company should be regarded as British, not only because of its being registered in the United Kingdom, but actually. If at the outbreak of hostilities some of the shares happened to be held by, say, German subjects, this in no way affected the British character of the concern, so long as the number so held represented a winger person of the agents. by, say, German subjects, this in no way affected the British character of the concern, so long as the number so held represented a minor portion of the capital. If the Council adopted the recommendation of the Works Committee it would, in his opinion, defeat the patriotic purpose and intention embodied in its previous resolution regarding British preference, and would also aid neutrals, and by doing so divert money from Imperial channels.

Rrifish Trade with Dussia: A Suddentian from Patrage.

divert money from Imperial channels.

British Trade with Russia: A Suggestion from Petrograd.

—In a letter received by us in reply to a communication addressed to the Russo-British Chamber of Commerce, 4, Gorochovaia, Petrograd, the Secretary says:—"In Russia there is a great desire to deal with British firms of high standing, and we ask you to kindly make known to your readers that any firms desirous of exporting their goods to Russia, or of appointing agents or opening branches here, can apply to this Chamber, giving references, and also send their catalogues for the Special Collection of Catalogues of the Chamber." We are sure that British manufacturers will not be slow to take advantage of this invitation.

British Trade with China.—Reuter's correspondent at Hong Kong reports that the local Hong Kong Press displays a good deal of anxiety concerning the outcome of the negotiations between Japan and China, and reflects feelings strongly held by British merchants in expressing a strong hope that an official announcement will shortly be forthcoming from the British Government demonstrating that no trade monopolies imperilling British commerce are to be apprehended.

apprehended.

apprehended.

Manufacturers and Electricity Works Extensions.—The Employers' Parliamentary Association, at a meeting held in Manchester recently under the presidency of Sir Charles Macara, adopted the following resolution:—"That this meeting is of opinion that permission should be accorded to the Manchester Corporation, and to other Corporations similarly situated, by His Majesty's Treasury, to raise fresh loans for the purpose of the extension of any electricity undertakings, as any refusal to secure permission would hamper to a very considerable extent those firms engaged on Government contracts who are dependent upon the Corporation for their supplies of motive power, and this Committee is emphatically of opinion that where it can be shown by any Corporation that the extension of electricity plant is necessary for an adequate supply of motive power on account or any Corporation that the extension of electricity plant is necessary for an adequate supply of motive power on account of the additional requirements of firms engaged on Government contract work, on application by the Corporation concerned, permission to undertake such extensions ought to be granted with all possible expedition."

Board of Trade Assistance.—The Commercial Intelligence
Branch of the Board of Trade has issued list No. 14 of Branch of the Board of Trade has issued list No. 14 of articles which enquirers desire to purchase. This list is of inquiries received during the week ended March 27th, and accessories—bells, black vitrite for lamp caps, caps for electric incandescent lamps, electric light fittings, ignition devices and accessories, insulators (moulded and porcelain), metal cases for pocket lamps, white flame carbons (18 m.m. cored) for lamps for photographic purposes; galalith material; lighting plant; searchlights; vibrators and electric massage machines; tungsten. sage machines; tungsten.

Munitions of War: Additional Labour.—With reference to the appointment of a Committee to take the necessary steps to provide additional labour for ensuring a sufficient supply of munitions of war, Mr. Herbert G. Riddle, Secretary, Society of Model and Experimental Engineers, writes to the "Standard" as follows:—"In view of the expressed opinions of the leaders of the Government as to the difficulopinions of the leaders of the Government as to the difficulties of manufacturing munitions of war and the acknowledged shortage of labour, the Society of Model and Experimental Engineers desires to call attention to the existence in this country of the considerable amount of mechanical ability and experience possessed by people who are not professionally occupied in engineering. No doubt many of these would be willing to offer themselves for service in professionally occupied in engineering. No doubt many of these would be willing to offer themselves for service in Government workshops if suitable conditions of employment could be arranged. The society suggests that the Government consider the formation of an industrial branch of the Royal Engineers, in which such men might enlist without the conformation of the such men might enlist. ithout having to conform to the existing military standards. The proposal might also attract trained workers whose services are not at present being utilised for Government work."

Anglo-Russian Trade.—At the meeting of the Hull Chamber in March, Mr. Bernard Barton presiding, a letter was read from Mr. A. Bournasheff, Russian Consul at Hull, stating that the success of German imports into Russia was stating that the success of German imports into Russia was due to (1) the adjustment of the manufacturers to the demands of the Russian markets; (2) the extensive credit given to Russian buyers; and (3) sending goods on commission, thus keeping stocks in Russia and avoiding the necessity of ordering the same every time from abroad. He suggested further that the success of British imports would depend upon the willingness of the English manufacturers to send their goods on credit and also on commission to Russia, and he gave the name of Mr. Teheremicinoff as the Russia, and he gave the name of Mr. Tcheremicinoff as the agency from whom reliable information as to credit of Russian firms could be obtained.—" Chamber of Commerce

Journal."
London Electrical Engineers (T.R.E.).—On Friday, March 26th, a dinner and smoking concert was held at the Feathers Hotel, Westminster, by No. 15 Squad of this Corps. An excellent programme made the time at their disposal pass very quickly, and a notable item of the evening was the presentation of a framed photograph of the members of the Squad to the Chairman and Instructor, Sergt. W. Robinson, who responded with an appropriate speech. The members were fortunate in being honoured by the presence, as guests, of the senior N.C.O.'s of the regiment, each of whom contributed a few well-chosen remarks. The proceedings closed with a vote of thanks to the Chairman, Auld Lang Syne, and the National Anthem.

ings closed with a vote of thanks to the Chairman, Auld Lang Syne, and the National Anthem.

International Metal-Workers.—The "Times" states that it is now proposed to change the headquarters of the International Metal Workers' Federation from Berlin to London. The membership, according to an official statement just issued, numbers 912,707. Germany is represented by 544,000, and Great Britain by 115,000. The new president of the British section is Mr. J. T. Brownlie, of the Amalgamated Society of Engineers.

No Obstacle to Recruiting.—The Bolton Transvays Com-

No Obstacle to Recruiting.—The Bolton Tramways Committee has authorised the manager to grant, without condition, permission to any employe who may wish to join the notwithstanding that men so leaving will necessitate

colours, notwithstanding that men so leaving will necessitate a reduction in service.

Personal.—The "Times" states that the Headquarters of the Mechanical Transport Column of the City of London National Guard Volunteer Corps are now at the offices of the Commercial Motor Users' Association, 83, Pall Mall, S.W., and that Colonel R. E. Crompton, C.B., has been appointed Hon. Commandant.

Mr. J. J. McMahon, electrical engineer in the overhead equipment department of the Manchester Corporation Tramways undertaking, was a passenger on the ill-fated "Aguila," which was recently torpedoed, but a message received in Manchester last week stated that he was one of a party who got safely away in a boat, and was rescued. He was taken on board the "Lady Plymouth," which proceeded to Madeira. Mr. McMahon has not been well recently, and, being one of the important officials in the service of the Manchester Corporation who had to forego his holiday last year, he decided to make a trip to the Canary Islands.

Mr. A. W. Mulliner of the Eccles Corporation electricity.

his holiday last year, he decided to make a trip to the Canary Islands.

Mr. A. W. Mulliner, of the Eccles Corporation electricity department, has been gazetted a lieutenant in the King's West Surrey Regiment.

Mr. John Hodgson, until recently an accounts clerk at the Anchor Cable Works, Leigh, who enlisted as a private in the Army Service Corps in September last, has worked his wor up until now he holds the position of warrant officer, although he is only 20 years of age. It is suggested that he is possibly the youngest warrant officer serving in H.M. Forces.

In a lengthy list of Aliens, to whom certificates of naturalization were granted during March, there appears the name of Morten Dahl Röer (Norway), electrical engineer, Leith, Roll of Honour.—Private J. H. Caine, of the 1st Loyal North Lancashire Regiment, formerly employed at the Darwen electricity works, has been killed in action. He was 40 years of age, and has left a widow and two children.

Private J. Barrett (single), aged 30, formerly a Manchester Corporation car driver, has been killed in action.

Private Frederick Harkness, 1st Battalion Grenadier Guards, a former employé at the Manchester Corporation Electricity Station, Dickinson Street, was killed in action on March 10th. He served through the Boer War, and reenlisted in his old regiment when the present war broke out.

enusted in his old regiment when the present war broke out. He leaves a widow and five children.

Mr. Albert Gay, borough electrical engineer, of Islington, has sent us a photograph of a Roll of Honour of the employés from the works—26 in number—who have joined the Colours. The roll, which is artistically designed, is the work of Mr. W. E. Bradshaw, the mains superintendent; the original is executed in colours.

#### TELEPHONE TROUBLES IN THE TROPICS.

BY W. LLEWELLYN PREECE, M.I.E.E.

(Abstract of paper read before the Institution of Electrical Engineers, on March 25th, 1915.)

The climatic and other consequent tropbles experienced give the engineer who is responsible for the maintenance of a telephone system in a tropical country more worry and anxiety in one week than his colleagues elsewhere experience in a year. The main troubles are due to the damp, and to the many natural effects caused by damp heat. In many places the humidity of the atmosphere varies between 80 and 90 per cent, and this damp heat produces a marvellone growth of cent., and this damp heat produces a marvellous growth of vegetation, while insect life is as prolific as the vegetation, and sometimes even more trying.

Lightning has a virulence unknown here. The electrical state of the atmosphere has an effect on the human nerves which seriously disturbs one's temper. Even wild animals do their best in some places to increase the engineer's labours. For instance, in some parts it is not unusual to have a mile or two of lines wrecked by giraffes, elephants, or monkeys. The giraffes roaming over the wilds of East Africa come up against a telegraph or telephone line; they have not the sense to draw back and duck their heads under the line, but they push on and on, carrying wires and sometimes the poles with push on and on, carrying wires and sometimes the poles with them. As similar troubles are experienced not only in telegraph systems, but also in heavy electrical installations, especially where overhead transmission lines are employed, the author hopes that this paper may be of some interest to all branches of the electrical engineering profession.

Instruments.—So far as white ants are concerned, we find that the use of teak practically prevents their ravages. A swarm of bee-like insects of Nigeria took a great fancy to use an instrument as a hive. Their entrance was the slot of the switch-hook, and the comb formed in the interior was cleated out many times, but each time it was re-formed by the insects, until in despair the engineer had the whole apparatus removed. The spider is a real pest all over the tropics; it builds for itself a nest in the telephone case, so that it is no

uncommon experience to find instruments entirely hors de combat from the work of this insect.

To circumvent the insect plague it is essential that these telephone cases should be sealed up as closely as pessible. The switch-hook should carry a brass plate which keeps the slot in which the arm works entirely covered. It is also desirable to have no terminally always the instrument, but to take the to have no terminals above the instrument, but to take the conductors through holes into the case and seal up these holes. Besides this, the internal wiring should be made as simple as possible; the wires must not be bunched together, but well stapled to the body of the instrument in separate ways. It is generally found that enamel insulation with a silk covering very suitable, though enamel insulation does not always give satisfaction.

In a tropical climate the ebonite sheath of a receiver may become soft and pliable; this is easily remedied by using blocked brass sheaths covered with enamel. In a tropical country a lot of trouble was caused by the insulating block which carried the contact springs in a capsule transmitter of a micro-telephone being warped by the damp heat, so that both springs touched the metal case of the capsule and short-

both springs touched the metal case of the capsule and short-circuited the microphone.

In most of the tropics the faults in the subscribers' instruments caused by lightning are very few, and so long as the engineer takes the precaution to fix the lightning protector at the point where the wires enter the house little trouble need be feared. Where the casual custom of fixing them near the instrument is followed it is not uncommon for the building to be set on fire. Until the protectors were fitted to the eaves of the roofs outside the building walls, the telegraph offices of Northern Nigeria were repeatedly burned down through lightning. lightning.

lightning.

The only other trouble likely to be experienced with the subscriber's instrument is that due to maltreatment by the subscriber himself. The tropical climate is not conducive to an equable temper. Even in this country the vagaries of the telephone cause occasional outbursts; there it is far worse. The owner of a large rubber estate complained bitterly time after time of his instrument; finally the engineer discovered that this subscriber was in the habit of using the mouthpiece of his micro-telephone, which hung from a wall-instrument by his desk, as a cigarette ash tray.

Exchange Switchboard.-Until lately the craving of the tropical engineer was to have the up-to-date central-battery system. There is, however, one obstacle in the way; the maintenance of really satisfactory insulation on overhead lines is almost impossible in the tropics, and if a pressure of 24 or 40 volts was applied to the line, even moderately fair working of the system would be extremely doubtful. The author has therefore set himself strongly against the central-battery board, unless a Government is prepared to place the whole system underground-which is usually prohibitive in cost see ing that some of the subscribers' premises are perhaps 20 miles or more from the exchange.

If this is the case with a central battery, what chance is there of satisfactorily maintaining an automatic system? Not only are we to expect insulation troubles with the high pressure on the lines, but there are also the intricate selectors and pre-selectors and other apparatus which would have to work in a climate capable of causing trouble even in a simple

magneto system.

At present the author is entirely in favour of a magneto system, using either mechanically-restored indicators or incandescent lamps controlled by relays.

Experience of enamelled wire has shown that in the tropics it is not altogether satisfactory, especially for small-gauge windings of coils. Two colonies had boards equipped with enamel-insulated wires throughout, but in a very short time various relays failed. On making inspection it was discovered that there were disconnections in their windings. On unwinding the coils, tiny green spots were seen, apparently caused by the damp acting on the copper. This could only be accounted for by assuming that these very fine wires do not, when passing through an enamel bath, pick up the enamel evenly, either there was at various points a very thin coating of enamel, or else no coating at all. As soon as these coils either there was at various points a very thin coating of enamel, or else no coating at all. As soon as these coils reached a tropical climate, the damp atmosphere, often laden with salt from the sea, soaked into the coil and acting upon the copper at these weak points ate it through. The only conclusion we can come to is that simple enamel insulation is not suitable for very fine gauge wires, but for all other purposes it certainly seems to give entire satisfaction. We are now in search of something more satisfactory for these coils, which cannot be said to be the case with either silk, cotton, or wool. These faulty coils are at present being replaced by others insulated with silk, the whole coil being then dried in a vacuum, and placed, whilst there, in a bath of "Voltalac," so that this insulating varnish may work its way right into the heart of the coil. It may possibly be sufficient to treat enamel-insulated coils with this "Voltalac," in which case there would still be the advantage of having the coils small. This will be tested shortly. The one drawback to the use of an insulating varnish is that, should any fault occur in it, the complete coil must be scrapped, as unwinding and rewinding on the spot is out of the question. On the other hand, faults in such a coil should be extremely rare, even in the tropics. the tropics.

Certain types of the mechanically-restored indicators have also given some trouble, especially the "eyeball" type. This is sometimes owing to dust and damp clinging to the eyeball and preventing it rotating. One board of this type which was sent to the tropics had the eyeballs mounted on steel pins; in a very short time these pins rusted badly and "seized." For tropical climates, wherever it is essential to use iron or steel the metal must be galvanised, "coslettized," or coated with some other non-rusting material. The plain metal rusts most rapidly and invariably leads to breakdown. Where phosphor bronze or gunmetal can be used, they are far superior to steel. Even the steel tips on the plugs, though used daily, will have a complete coating of rust in the morning after the night's rest.

The question of operators causes the traffic department con-

Ing after the night's rest.

The question of operators causes the traffic department considerable worry. In the majority of tropical places it is impossible to employ European operators; for such work the Governments have to rely on half-caste girls or native men, neither of whom, with rare exceptions, have mental equipments comparable with those of European women. With the only available operators, 60 lines to a position is all that can be managed in some places, and 80 lines per position is generally quite as much as can be handled.

One other most trying and frequent worry in an exchange

One other most trying and frequent worry in an exchange is the objection that subscribers have to "ringing off" after a conversation. To avoid this source of annoyance and the consequent delays in freeing cord circuits, an automatic clearing signal has been fitted to all the boards in the Malay States, was to these for 50 subscribers.

ing signal has been fitted to all the boards in the Malay States, even to those for 50 subscribers.

Line.—The normal type of overhead construction now employed in most tropical countries is fairly well standardised. The poles used are either wrought-iron taper tubes with castiron bases, or are built up of tubes of riveted sheet steel. In most parts it is hopeless to use wood poles, owing to the prevalence of white ants, which in a very few years demolish the whole of the interior of such poles. The arms, on the other hand, are fairly often of this material, for the white ant will not work its way up 15 or more feet of iron tube to reach these arms, and in some countries most excellent hard wood is obtainable locally.

Where hard wood is not obtainable, tubular iron arms are

Where hard wood is not obtainable, tubular iron arms are employed. These arms carry 6, 8, or 12 Cordeaux porcelain insulators, mounted on iron stalks. The very best practice is followed as regards workmanship and finish, yet the average

insulation of these lines is very low. The atmosphere, with a humidity of 80 or 90 per cent., naturally has considerable effect in reducing the insulation resistance.

A more troublesome factor, however, is the vegetation; more troublesome in that, whilst the clearing away of these trees would be of very great assistance in keeping up the insulation

would be of very great assistance in keeping up the insulation resistance, the high cost of doing this in most places, and the reluctance of the Government and the public to allow this work to be carried out, hamper the engineer.

In the towns and suburbs underground cables would obviate the trouble; outside the towns, however, the roads run through dense jungles or thick plantations of rubber trees or coco-nut palms. The normal clearing for roads is 60 ft., but in practice such a clearance is often not maintained: and with even palms. The normal clearing for roads is 60 ft., but in practice such a clearance is often not maintained; and with even 60 ft. clearings the line must be within 20 ft. of the trees at the best, and is actually often less than 10 ft. Unless a further 50 ft. clearance is made on the side of the line away from the road, and properly maintained, contacts and breakages due to falling trees must remain almost a daily experience. The falling trees must remain almost a daily experience. The expense of keeping down the undergrowth is also a consider-

able annual charge.

Another line trouble that the tropical engineer is bound to experience is caused by insects, some of which delight in making their homes between the petticoats of insulators. The making their homes between the petticoats of insulators. The author has seen an insulator so covered with a spider's nest as to be itself invisible, the base of the nest being on the arm and the apex above the insulator. Constant attention on the part of the line men is necessary to prevent the insects getting such a hold on the insulators. It is quite usual to find, formed in a single night, webs glistening with dew and connecting the wire to the insulator stalk, the insulation resistance of the line being reduced as a result to a few ohms. Oil insulators are useless. Mr. Guthrie Spain, the telegraph engineer of British Guiana, first brought to the author's notice the fact that insects will not enter glass insulators. The author is told that glass insulators are used in Cuba for this reason. Apparently these insects prefer a dark place for

author is told that glass insulators are used in Cuba for this reason. Apparently these insects prefer a dark place for their home, which obviously is not the case when the insulators are made of glass. The author is inclined to think that if oil insulators of glass could be easily obtained, considerable improvement in the insulation should result.

Another widespread source of line trouble in the tropics is lightning. In many places thunderstorms are of almost daily occurrence throughout the greater part of the year. In certain towns a single storm will often result in 50 per cent. or more of the subscribers' telephone lines being carthed at the pole boxes, this being caused by the strong discharges through the protectors to earth, which carry so much carbon dust across the gap as to place the two carbon blocks in contact; so that practically after every storm a number of line men had to be sent to all those boxes to clean the protectors.

sent to all those boxes to clean the protectors.

rather of the me had to be sent to all those boxes to clean the protectors.

This trouble can, however, be cured to a great extent by using the vacuum type of protector, in which the two carbon blocks are inserted in an exhausted glass tube, the opposite surfaces being serrated and fixed about 1/16 inch apart. These protectors are now used to a considerable extent by Mr. Cadman in the Malay States, and are, the author believes, found to be quite satisfactory. Occasionally an extra heavy discharge will burst the tube, but they are very easily replaced. This possibility, however, makes it essential that fuses shall also be inserted, for if a discharge were so heavy as to burst the protector, the line would be no longer protected and a subsequent discharge might damage the cable seriously.

The one disadvantage of these protectors was their size, which involved the use of a very large pole box, even for 25 lines; but a new type of box designed early this year has practically solved this difficulty. An earthed iron wire stapled to the tops of the poles, and also connected to their earth-wires, has been found most effective in guarding the lines from lightning.

lightning.

For underground work in the tropics the usual practice is For underground work in the tropics the usual practice is to use armoured lead-covered air-space cables terminating in boxes on distribution poles, and hitherto the engineers have fellowed the British Post Office practice of making the joints so that dry air can be periodically pumped through. The author is inclined to think that the American solid joint would give much less trouble. If the cable were well sealed with paraffin wax immediately it was opened for jointing, the damp could not enter it unless the lead covering was damaged. If parainn wax immediately it was opened for jointing, the damp could not enter it unless the lead covering was damaged. If such an accident did happen, the length would have to be replaced. Exactly the same result must, however, occur if the practice is to employ open joints and dry air pumping. Once the damp has the chance of entering a cable in the tropics, no amount of pumping will drive it out completely, and the length must be replaced without much delay.

Armoured lead-coloured cables are normally very free from faults, except those due to damage gauged by men working on

faults, except those due to damage caused by men working on the roads. There is in Shanghai a curious flying insect which is able to bore holes in which to lay its eggs in the lead cover-ing of overhead cables, but the author knows of no case in a tropical country where an insect has damaged an armoured lead-covered cable, or where the damp has caused faults if the it has been found desirable to lay the cables in troughs filled with bitumen, but otherwise armoured lead-covered cable gives extremely little trouble.

Staff.—The last trouble peculiar to the tropics to which the uthor wishes to refer concerns the local staff. It would obviously be far too expensive to obtain from England not

only engineers, but inspectors, foremen, and line men. Speakonly engineers, but inspectors, foremen, and the identification generally, no white man can live in the tropics—with any pretension to comfort—on less than £250 per annum; and in countries where the men have to pay for their voyages home and back when leave is granted, they should receive about £300 per annum if there is to be any chance of keeping them. 4:00 per annum if there is to be any chance of keeping them contented. As such salaries are prohibitive, native labour is essential for the lower grades on the technical staff. Unfortunately, whilst these natives can be trained by the engineers, they must, unless a complete white superintending staff is provided, be left very largely to look after themselves in carrying out their duties. Most natives have not the smallest conception of responsibility, nor have those who are made inspectors any power of command. Thus the engineering department is largely dependent for the maintenance of lines on native linearen, who are very much inclined to neglect department is largely dependent for the maintenance of lines on native linemen, who are very much inclined to neglect their work, and on native inspectors who have no power of controlling these linemen, and who are equally ready to slack; whilst in the majority of the tropical colonies the chief engineer is kept too short of technical assistants to allow of proper supervision of this native staff.

This is largely due to the somewhat unfortunate but universal practice of making the telegraph and telephone department a branch of the Post Office. For as the engineer department a branch of the Post Office. For as the engineer is a subordinate officer in the postal department, he naturally ranks with postal subordinate officers, although the whole responsibility of the maintenance and extension of the telephone and telegraph systems of the colony rests on his shoulders. In consequence of this practice, the engineer's salary is in every case lower than it should be. Further, as his superior officer and the heads of the Government are very rarely technical men, they are unable, in many cases, to appreciate the desirability of the engineer's proposals, nor do they realise the importance of allowing the chief engineer a sufficient number of trained assistants, or, often, of granting reasonable salaries.

reasonable salaries.

As it is now, the technical appointments in all tropical colonies are too few, and as even these are not made sufficiently attractive, it is difficult to fill them.

The tropical engineer, taking things all round, richly deserves our sympathy and also the esteem of the profession for the way in which he steadily tackles this trying work, though almost invariably under-rated, under-paid, and overworked worked.

#### OUR LEGAL QUERY COLUMN.

"LAW-LESS" writes:-"Can you inform me if a municipal authority which possesses no special powers with regard to wiring, hiring, show-rooms, etc., is legally justified in opening show-rooms for the display of fittings, apparatus, etc., provided that no articles are disposed of, inquirers being referred to contractors or manufacturers?

"In the recent case of the liford Gas Co. v. liford Council, judgment was given against the defendants on various points, one being that of their show-room, which was ordered to be

closed.
"In a note in one of your contemporaries of the 18th inst., it is stated that when the Doncaster and Dewsbury Bills were recently before the House of Lords Committee, a representative of the Board of Trade stated there was no need to include the clause relating to show-rooms, as all authorities already had these powers under the General Act. Is this so and, if so, where may these powers be found as I cannot trace them?"

*• It is difficult to understand why the contention referred to in the last paragraph of this query was allowed to prevail before a Committee of the House of Lords, because there is no before a Committee of the House of Lords, because there is no public Act of Parliament known to this writer which confers any such rights on local authorities supplying electricity. In his notes to S.25 of the Electric Lighting Act, 1882, the learned editor of "Will's Law of Electric Lighting" writes:—"In the absence of statutory authority, undertakers who are a local authority cannot provide lamps, fittings, motors, or apparatus other than meters which are provided for by Ss. 52, 55, and 56 of the Schedule to the Electric Lighting (Clauses) Act, 1899. . . . It is now quite common to find in the special 52, 55, and 56 of the Schedule to the Electric Lighting (Clauses) Act, 1899. . . . . It is now quite common to find in the special Acts of local authorities a clause enabling them to sell, let, hire, etc., but not to manufacture lamps, meters, electric fittings, apparatus, etc." He cites, as illustrations, the Acts obtained by the following towns: Nottingham, Manchester, Halifax, and Leith. In London, of course, the borough councils are authorised to supply fittings by the London County Council (General Powers) Act, 1906 (6 Edw., 7c. cl.).

As to the first question, if a local authority may not expend the ratepayers' money in the business of selling fittings, it seems reasonable to suppose that no expense must be incurred on things ancillary to such a business.

Prices Advance. — The British Thomson-Houston Co., Ltd., announce that from April 7th there will be a 10 per cent. advance on the price of their electrical fittings.

## BUSINESS NOTES.

Catalogues and Lists.—Messes. J. H. Tucker & Co.,

King's Road, Hay Mills, Birmingham.—Illustrated and priced folder relating to their new pattern ironclad switches.

MESSES. BERGTHEIL & YOUNG, LTD., Finsbury Court, London, E.C.—Booklet containing illustrations and brief particulars of "Bandy" patent single-phase motors. The pictures all particular photographs of certain installations the motors being present for

E.C. — Booklet containing illustrations and brief particulars of "Bandy" patent single-phase motors. The pictures all represent photographs of actual installations, the motors being used for crane driving, pumps, lifts, transporters, printing presses, &c.

THE COVERTEY CHAIN CO., LTD., Spon End Works, Coventry.

—Pamphlet emphasizing the silence of the "Coventry" chain drives. Also a 72-page catalogue (Engineering Section), very fully illustrated, describing the "Noiseless" chain and its principle and the methods of guiding it on the wheels. Many pages are occupied with tabulated data relating to wheel sizes, chain lengths, teeth, hints to users, and so forth.

teeth, hints to users, and so forth.

MESSRS, P. E. CHAPPUIS & Co., 85, Fleet Street, London, R.C.

—8-page illustrated and descriptive price list of Chappuis's trough'
reflectors for "Striplite," tubular and ordinary tungsten lamps;
also "Conoid" silvered reflectors.

MESSES. W. N. BRUNTON & SON, Wire Mills, Musselburgh.—
40-page pocket catalogue giving tabulated particulars and prices
of their silver steel, drill rod steel, high speed steel rods, and steel
wires for hardening and tempering. Copies will be sent to any
interested reader on application.

MESSES. HIGGS BROS. Sherbourne Road, Balsall Heath. Birming-

MESSES. HIGGS BROS., Sherbourne Road, Balsall Heath, Birmingham.—20-page catalogue containing illustrations of their motor-generators and booster sete, brushgear, "C" type shunt and series motors, from 16 to 25 H.P., "C" type shunt generators, controlling gear, starting switches, &c. A special copyrighted system of list-ing dynamos is adopted. Prices and dimensional and shipping particulars are tabulated.

TEMPLE PRESS, LTD., 7-15, Rosebery Avenue, W.C.—New catalogue of technical manuals, touring handbooks, &c. BRITISH THOMSON-HOUSTON Co, LTD., Rugby.—Illustrated price list No. 7,100B, giving particulars of B.T.H. fan motors and exhaust fans.

Staff Supper.—About 30 members of the headquarters (Manchester) supply department staff of the British Westinghouse Electric and Manufacturing Co., Ltd., sat down to an excellent hot-pot supper at the Exchange Hotel, on Monday evening, March 29th. Afterwards there was a smoking concert, at which Mr. J. Gibson (manager of the supply department) presided, 50 members of the supply staff and a few specially invited guests being present. During the evening the chairman said that so far as the turnover of the department was concerned they had been successful to the extent of an increase of about 30 per cent. He felt sure they missed several old faces, particularly that of his chief assistant, Mr. G. Ellam. As they all knew Mr. Ellam had been away many months in Russia, and he was doing good work for the department. Before sitting down he asked them to drink silently to the memory of those who owing to the war would never return. During the evening the following toasts were enthusislastically honoured:—"The King," proposed by Mr. J. Gibson; "His Majesty's Forces," by Mr. L. E. Wilson; "The Westinghouse Co.," by Mr. W. S. Robson, this toast being responded to by Mr. W. J. Hollick; "Our Visitors," by Mr. A. Pougher, responded to by Mr. J. Gibson. The following artistes contributed to the entertainment of the company:—Meears. A. Pougher and T. Jackson as pianists, Mr. A. Pougher (flautist), Mr. T. E. Kenyon (humorist), Mr. T. Clough (elecutionist), Mr. Mr. C. C. Oakley (baritone), Mr. W. S. Robson (violinist), Mr. McColl (humorist), Mr. F. Freeman (elecutionist), Mr. D. E. Elliott (Newcastle dialect recitation), and the "Inharmonius Four," who caused great merriment by their vocal efforts. The proceedings terminated with the singing of "Auld Lang Syne" and "God Save the King." Staff Supper.—About 30 members of the headquarters

Charge of Stealing. — Sentence. — Before Judge Rentoul, at the Central Criminal Court, on Tuesday, Raoul de Redon, 32, electrician, pleaded guilty to counts of an indictment charging him with stealing one electric battery, and one X-ray tube, the goods of the Governors of the London Homeopathic Hospital, one X-ray tube and one milliamperemeter, from the West London Hospital, one X-ray tube from the Royal Free Hospital, and similar articles from Hampstead General Hospital, and Guy's Hospital. Counsel for the prosecution said that, for some time past various articles had been missed from the surgical departments of London Hospitals, and, information being given to the police, inquiries were made, which resulted in the arrest of the accused, who, it was alleged, had been found dealing with the stolen articles, soon after the thefts, for sums of money considerably below their cost price. It was stated that the hospital authorities had been put to the greatest trouble and inconvenience in conhad been put to the greatest trouble and inconvenience in con-sequence of the theft of X-ray apparatus and other surgical appliances. Judge Rentoul sentenced the prisoner to three months imprisonment in the second division.

Liquidations. — OTIS ELEVATOR Co., LTD. — This company is winding up voluntarily, with Mr. R. P. Sellon as liquidator. A meeting of creditors is called for April 14th.

SPANISH NATIONAL SUBMARINE TELEGRAPH Co., LTD.—This company is winding up voluntarily, with Mr. J. Jeffery, of 106, Cannon Street, E.C., as liquidator. A meeting of creditors is called for April 12th for April 12th.

Bankruptcy Proceedings.—George I. T. Parfitt, 11, Priory Road, Keynsham, near Bristol, Somerset, consulting electrical engineer.—The receiving order in this matter was made on the petition of a creditor, the act of bankruptcy being the failure of the debtor to comply with the requirements of a bankruptcy notice served upon him. According to the statement of affairs the liabilities amount to £2,024, to meet which there are no assets. It appears that until 1888 debtor was employed as an electrical engineer, but at that date he and his brother-in-law took over the book debts and liabilities of an electrical engineering business carried on at 9, Denmark Street, Bristol. They paid £320 for the goodwill and stock-in-trade, and continued the business under the style of Parfitt, Webber & Co. Debtor introduced a capital of about £300 on commencing, and has since put in further capital, amounting to about £1,700, while his partner has from time to time introduced capital of about £600. In 1912 the partnership was dissolved, the partner going to South Africa, but no formal dissolution took place, and the business was continued by the debtor. The partner returned from South Africa about the end of 1913, and on January 20th, 1914, they transferred the business to the Colston Electrical Works, Ltd., in consideration of £1,650, payable in £1 ordinary shares, of which £50 were allotted to Mr. Webber (the partner), £50 to the debtor, and £50 to his sister, in consideration of moneys advanced to the firm, 200 to the manager trical engineer, but at that date he and his brother-in-law took in consideration of moneys advanced to the firm, 200 to the manager of the business for wages and money advanced, and 100 to Mr. E. Brock for services rendered to the firm prior to and on the formation of the company. The company took over the whole of the assets and liabilities, with the exception of £420 owing to seven trade creditors and the overdraft at the bank, which amounted to about £750. Certain payments have since been made to these trade creditors on account of their claims. Debtor has undertaken several contracts for the supply of electrical plant and fittings. A full set of books was kept prior to the sale of the business to the company, but no books of account have been kept since that time. The failure is due to losses for goods supplied to, and through guarantees given for, a certain firm, which went into liquidation, and loss of business occasioned by the war, and debtor admits knowledge of his financial position last October. The following are the creditors:-

Trade Announcements. -- Messrs. Parmiter, Hope AND SUGDEN, of Manchester, have opened a London office at Queen Anne's Chambers, Westminster, under the direction of Messrs, Nathan & Allen. Samples of the new Fluvent fuse system may be en there.

MESSES. NEWTON BROS, electrical and mechanical engineers, of Derby, have converted their business into a limited company (Newton Bros. (Derby), Ltd.). All debts and liabilities of the firm are undertaken by, and all debts due to the firm are to be paid to, the company. The directors are Mr. C. A. Newton, Mr. R. Newton the company. The directors are Mr. C. A. Newton, Mr. R. Newton and Mr. H. Newton, and the constitution and control of the business will be precisely as heretofore, the alteration not in any way interfering with the management or scope of the undertaking.

Larger premises at 329, Lord Street, Southport, have been opened by MESSES. T. WAINWRIGHT & SONS, LTD., electricians.

Italy.—An agent in Milan desires to represent United Kingdom manufacturers of parts of electrical and mechanical plant. Inquiries should be addressed to the British Consulate, Milan.

## LIGHTING and POWER NOTES.

Australia.—According to the Sydney Evening News, an agreement was practically reached between the North Sydney Council and Sydney City Council, for the latter to carry out the electric lighting in North Sydney.

The proposal for the Sydney Council to purchase a coal mine

has now been abandoned.

Singleton (N.S.W.) is considering the question of an E.L. installation, and two estimates have been obtained.

Barking.—New Plant.-—The Electricity and Tramways Committee has adopted the recommendation of the acting electrical engineer for the installation of a 1,000-kw. Ljungstrom turbine set at the electricity works.

Barrow.—Loan Sanction.—The L.G.B. has sanctioned the borrowing of £12,500 for the electricity undertaking. The Council approved of £124 being distributed amongst the staff of the electricity works as remuneration for the extra work thrown money it in approximation with the extra work thrown upon it in connection with the extensions carried out during the past 18 months.

-The T.C. has decided to apply to the Blackburn.-B. of T. for consent to the construction of a generating station on land at Whitebirk recently leased by the Corporation.

Boston.—E.L. SCHEME.—The R.D.C. has, on the invitation of the B. of T., decided to send representatives to confer with other interested parties on the proposed E.L. scheme for the district

Cahir (Co. Tipperary).—Proposed E.L.—A public meeting has considered proposed increases in the prices of gas, and decided to form a company for the introduction of electric lighting. A committee was appointed to deal with the matter.

Chelmsford.—RESTRICTED LIGHTING.—The Electric Supply Corporation, Ltd., has offered a rebate of £112 in respect of the public lighting account for the quarter ending December 31st, on account of the restricted lighting.

-A Sub-Committee of the T.C. is considering the question of adopting an optional system of charging for electricity on the rateable value basis, with a secondary charge of, say, id. per unit for current consumed through one meter for all

Croydon.—The charge for electrical energy for lighting on the flat rate has been increased by \( \frac{1}{2} \)d. to 4d, per unit as from March 25th. It was stated that the increased cost of coal was equivalent to an increase of £9,000 per annum; the extra charge would bring in £3,000 to £3,500. The Committee is going into the question of increasing the charge to the tramways, which it is believed, with one exception only, is the lowest in the kingdom.

Darlington.—Proposed Loan.—A loan of £3,400, to cover the cost of additional plant required for the proposed supply to the North-Eastern Railway Co., has been applied for by the T.C.

Dublin.—ELECTRICITY REPORT.—In compliance with the resolution of the T.C., the city treasurer and city accountant have issued a report on the financial side of the Corporation elechave issued a report on the financial side of the Corporation electricity undertaking for the seven years ended March 31st, 1914. This contains a great many figures, from which we abstract following:—Total capital borrowed, £790,717; indebtedness, £592,844. Deficits since 1907-8 total £16,270 and surpluses £30,814. The amount paid by levy from the rates was £4,147, and paid by the undertaking in relief of rates, £5,500. The consumers increased from 1,687 in 1908 to 6,372 in 1914, and the units sold from 2,720,226 to 7,091,729 in 1914.

During the seven years to March, 1914, £399,811 was expended on capital account. The total amount levied upon the rates since the incention of the undertaking in 1891 was £52,174, the net

the inception of the undertaking in 1891 was £52,174, the net amount standing at £46,674 for 23½ years. In the last 10 years no charge has been made on the rates, and some £1,363 has been

no charge has been made on the rates, and some £1,363 has been paid in relief of them. In the five years to 1913-14 the revenue from consumers rose from £38,354 to £87,810; for the year 1914-15 to March 18th receipts from private consumers (excluding Corporation departments) amounted to £85,733, an increase of £10,813 on the corresponding figure of the previous year.

While power and heating supplies increased to over 48 per cent. of the private supply in 1913-14, the load factor only increased from 13'47 to 13'99 during seven years, and the reporters suggest consideration of the regulation of the proportion of the power and heating supply, and the possibility of some differentiation in power rates to ensure that current shall be sold at an economical figure. They also agree with the proposed temporary increase in figure. They also agree with the proposed temporary increase in price put forward by the Electricity Committee.

Gillingham (Kent).—() wing to the increased cost of fuel, &c., the T.C. has, from April 1st, increased all rates for current for lighting by †d. per unit.

Mesers, E. J. & W. Goldsmith have asked for an estimate for the cost of connecting the Rainham Cement Works with the mains.

Elland, -- The Council has advanced the price of current for lighting purposes, and the prices for power supply will probably have to be increased.

-Proposed Loans.—The T.C. has been informed that the application for a loan of £1,000 for services, cannot at the present time be sanctioned, and in consequence no connections will be made until the end of the war to premises where mains do not already exist. A further loan of £8,000 for plant extensions was about to be asked for, but has been abandoned.

Heywood.-Loan Sanction.-The L.G.B. has sanctioned the borrowing of £6,440 for electricity purposes.

Holmfirth.—E.L. Scheme.—The U.D.C. has defined the compulsory area on which work should be commenced under the electric lighting order, and has also decided that the building of the generating station should be let by tender in one contract.

Irish Water Power Schemes.—A private company has been formed to carry out extensive electric supply schemes at Belleek in the north, where the waters of Lough Erne would be used, and at Limerick, in the south, where it is proposed to utilise the River Shannon.

Japan.—The Japanese Department of Communications has just issued a revised series of regulations in connection with electrical undertakings in Japan, particularly those connected with the generation and distribution of electrical energy for power purposes. Among the new regulations are conditions with regard purposes. Among the new regulations are conditions with regard to standard periodicities and distribution pressure, provision for the transmission of current from one system to another in case of breakdown, simpler formalities for the conveyance of power plants in accordance with the Factory Mortgage Law, and the stricter enforcement of the official inspection of private companies, power distribution, and supply terms and procedure.

Keighley.—The T.C. has decided, in response to the L.G.B. circular endorsing the requirements of the Committee of Imperial Defence for more army recruits, to permit those of its servants who are not absolutely indispensable to enlist or enter urgent

servants who are not absolutely indispensable to enlist or enter urgent Government services, and that no men of military age, unless they have been rejected in respect of army service within a month previous to the application, should be accepted for employment in the Council's works departments.

The Electricity, Gas and Water Committees have been instructed to confer as to the best means of avoiding a danger arising out of the possibility of the fusing of gas mains which are laid near electricity cables; it was reported that recently an 18-in, trunk gas main had been fused near a large works in the town.

Kingstown. — ELECTRIC SUPPLY ARBITRATION. — Last week Mr. Justice Barton, in the Chancery Division of the Irish High Court, granted an application by the Dublin Southern District Electric Supply Co., Ltd., making an arbitrator's award as to the payment of £3,608, as the price to be given by the Kingstown Urban Council for the electric lighting undertaking a rule of Court. The solicitors for the Dublin Southern District Electric Sapply Co., writing to the Dublin Press, point out that the Arbitrator by his award decided that the Kingstown Council should pay £3,608 for the undertaking; the Arbitrator's fees, amounting to £183; and the costs of, and incidental to, the arbitration proceedings and the award. Further, it was pointed out that the Kingstown Council, notwithstanding the fact that a letter had been written to its solicitors that the deed of transfer would be returned approved of immediately the order was obtained, filed an affidavit to prevent the obtaining of an order, thereby compelling - ELECTRIC SUPPLY ARBITRATION. affidavit to prevent the obtaining of an order, thereby compelling the company to bring the motion which had been decided by Mr. Justice Barton. The costs against the Council, and their own costs, will amount to £30.

Leyton.—New Plant.—Application is to be made to Leyion.—New Plant.—Application is to be made to the L.G.B. for sanction to borrow £1,000 in respect of new services. The Electric Lighting Sub-Committee has had under consideration a report of the electrical engineer in regard to the necessity of providing additional plant at the generating station, at a cost of £17,158, and in connection therewith an offer of the Hackney B.C. to give a bulk supply. The Council has decided on the provision of additional plant as recommended by the engineer.

London.—Woolwich.—The B.C. has received a letter AORIGON.—WOOLWICH.—I he B.C. has received a letter from the L.C.c. with regard to the application for the balance of the loans required in connection with Globe Lane works extension. In this letter the County Council's Finance Sub-Committee states that it is now in a position to deal with the Borough Council's application for £35,000, but that the balance (£13,000) will have to stand over until a more detailed statement is supplied by the Borough Council, showing how the total estimated of these extensions which amounts to no less than £77,000 is a winder. extensions, which amounts to no less than £77,000, is arrived at. From a statement of the loans to be dealt with, it appears that the total amount of loans granted for 42 and 39 years for plant and machinery is £64,732, and the condition proposed to be attached to the Council's loan sanction is that the amount outstanding at April 1st, 1920, in respect of this sum be repaid within one half of the periods then provided of the learning that one-half of the periods then unexpired of the loans in which the amount in question is included. Subject to this condition, the Sub-Committee has agreed to recommend sanction to the borrowing of £35,000, as follows:—Buildings, £9,000, 30 years; plant and machinery, £26,000, 15 years. The Finance Committee of the B.C. recommends the Council to accept the conditions attached to the

County Council's sanction to the \$35,000, it being understood that County Council's sanction to the £35,000, it being understood that no further conditions will be imposed when the further balance of £13,000 yet required is dealt with. At a meeting of the B.C. this recommendation was agreed to. H.M. Office of Works has given the B.C. permission to wire some 200 houses, forming a portion of the Government housing scheme at Eltham, and to provide the necessary fittings, including lamps. Application is to be made to the L.C.C. for sanction to borrow £2,172, the cost of carrying out the work. In addition, it will cost £443 to provide the necessary transformer, kiosk and services.

KENSINGTON.—The General Purposes Committee of the B.C. has considered a letter from the Notting Hill Electric Lighting Co. relative to a proposal to increase the price of current from 5d. to 5ld. per unit, and suggests that this should be assented to by the Conneil.

Maidstone.—Increased Charges. — The T.C. has decided owing to the extra cost of coal, to increase the price of current for lighting and heating by \( \frac{1}{2} \)d. per unit from April 1st, and by \( \frac{1}{2} \)d. for power as from January 1st.

-A letter has been received from the Manchester. -L.G.B. stating that the sanction issued on August 15th, 1908, authorising the borrowing of £1,600 for the purposes of the electricity undertaking, has been cancelled.

Richmond-on-Thames.—The Electric Supply Co. has informed the B. of G. that the price of current has been increased by 10 per cent.

Salford,—Great dissatisfaction is felt by the inhabitants in connection with the lighting of the streets of the borough, and the attention of the Military Authorities has been called to the state of affairs.

The Electricity Committee has given instructions that no further extensions of mains and services be carried out during the war except in those cases where, in the opinion of the electrical engineer, they are absolutely necessary.

Sheffield. -L.G.B. Inquiry.—An inquiry was held on the 31st ult. relative to the Corporation's application for sanction to borrow £164,373 for extensions to the electricity works and plant, to enable it to supply much needed assistance to the large armament works which are now engaged at top pressure on Government orders.

South Africa.—A ratepayers' meeting has been called for April 23rd to adopt a resolution to borrow £15,000 for providing for the cost of the hydro-electric scheme at Worcester, Cape Province.

The East London (Cape Province) T.C. proposes to spend \$20,034 on the electricity supply undertaking for extensions and additions at the power station and to the distribution system.

The Wellington (Cape Province) Municipality proposes to borrow the sum of \$1,500 for extensions to the electric light works and the

purchase of fittings and accessories.

Southampton.—Year's Estimates.—The estimates of the Electricity Committee show that it is expected to receive £53,860 from the sale of energy, meter rents, and miscellaneous receipts during the ensuing year. This represents an increase of £758, as compared with the actual amount received during 1914-15, and a decrease of £3,614 as compared with the estimate for that year. Expenditure during the next 12 months is estimated at £36,408, leaving a gross profit of £17,452, as against £19,940 for 1914-15, and for which the estimate was £21,201. From this amount has to be deducted £16,254 in respect of interest and redemption charges, and £1,100 for special expenditure, leaving £98 available for appropriation. This figure compares with £230 during 1914-15, and £1,948 the estimate for that period. The Electricity Committee is considering the question of extinguishing street lamps at midnight between March and September. Southampton.—YEAR'S ESTIMATES.—The estimates of

Stockton-on-Tees.—L.G.B. Inquiry.—An inquiry was held on March 30th into the application by the T.C. fer sanction to a loan of £10,100 for mains, services, and rotary converters, &c.

There was no opposition, and it was explained that current was
being largely supplied to shipyards and works engaged on Government work, and that the extension of plant was urgent.

Swansea.—An official inspection has been held of the new three-phase plant at the electricity works, estimated to have cost in all some £40,000. The Mayor started up a new Curtis

Torpoint.—E.L. SCHEME INAUGURATED.—The public lighting scheme of the Torpoint Electrical Supply Co. having been completed, the new generating station was opened by Lady Beatrice Pole-Carew on the 31st ult. The constructional work was carried out by Messrs. Brooking & Co., of Exeter, and about 90 public lamps are to be lighted.

Upper Greetland.—The Yorkshire E.P. Co. has applied to the B. of T. for consent to the erection of overhead lines in the district for the supply of current at a pressure of 400 volts.

Venezuela.—La Compania Electro-Industrial de Barquisemeto is the name of a new undertaking that has lately been organised, with a capital of £20,000, to establish an electric lighting station and ice-making plant in the town of Barquisemeto.

Worthing.—Public Lighting, &c.—The Electricity Committee of the T.C. has been considering the question of revising the charges for electricity supplied for public lighting. The Highways Committee has agreed to a new arrangement for paying Highways Committee has agreed to a new arrangement for paying the actual capital and maintenance charges on so much of the plant as is provided for public lighting purposes plus the actual running cost of producing the current supplied. Had this system of charging been in operating during the whole of the past financial year it would have meant a saving of £242, as compared with the system of charging a flat rate. The expenditure on the electric light account during the past year totalled £11,497, the income amounted to £11,453; an estimated surplus of £617 became an actual deficiency of £44. In the financial year ending March, 1914, the undertaking contributed £500 of its surplus to the district fund for the reduction of the rate.

Worcester.—L.G.B. Inquiry.—Mr. H. R. Hooper resumed the inquiry last week into the application of the City Council for sanction to borrow £5,250, £1,973 and £800 for purposes of the electricity undertaking. The inquiry was adjourned for the preparation of particulars of the expenditure on loans previously granted. The inspector stated that the Treasury would not sanction loans for any extension of the undertaking unless it was necessary for war purposes, and pointed out there was an excess expenditure on loans of £1,959, which was as far as they could deal with the application: the other part must stand over. could deal with the application; the other part must stand over.

## TRAMWAY and RAILWAY NOTES.

Australia.—Twenty-six municipalities in the Melbourne area have held a conference to discuss the question of damage to roads by motor traffic, and the provision of means to regulate such traffic. A committee strongly recommended some form of special taxation of motor-'buses, which are the worst offenders, to be based, it was suggested, on mileage run.

Bolton.—WAR BONUSES.—A scale of war bonuses has een prepared to apply to adult or married workmen in the various

Corporation departments whose wages in any week do not exceed 30s. The bonuses range from 3s. down to 6d., and their payment will involve an annual expenditure of £3,700.

The Tramways Committee has under consideration a letter from the Electrical Trades Union making application on behalf of those members who are employed in the tramway department for an increase of 5s. a week in wages.

-According to the Financier, the Pernambuco Tramways and Power Co. has at length succeeded in running cars in the more central parts of the town. Some considerable time must elapse before the electric tramway system reaches the suburbs where it is much needed, as the existing system, which has been bought by the company, is quite inadequate. An arrangement for lighting the city, made with the same concern, has now been in operation for nearly a year, with satisfactory results.

Bristol.—TRAMWAYS PURCHASE.—We understand that in addition to the gentlemen named in our issue of March 26th, Mr. H. Faraday Proctor, the city electrical engineer, was also nominated by Sir John Snell to take part in the joint valuation of the sections of the Bristol tramways which are purchasable by the

Dunfermline. — TRAMWAY INQUIRY. — Under the Dunfermline. — TRAMWAY INQUIRY. — Under the Private Legislation Procedure Act an inquiry has been held in Edinburgh in connection with the Dunfermline and District Tramways (Extension) order. Power was sought to construct a tramway from Dunfermline to Rosyth by what was known as the Queensferry Road route. The Burgh of Dunfermline and the Earl of Elgin objected to the scheme on the ground that a tramway linking up the same districts by the Grange Road route had already been authorised. It was stated that in the event of the Grange Road route not being constructed the Dunfermline town planning scheme could not be carried out.

After Counsels' addresses, Lord Wemyss announced that subject to the adjustment of clauses and to a promised addition to Clause 4, the Commissioners unanimously found the preamble proved. The effect of the addition to the clause is that the company will construct, within 18 months from the commencement of the order,

struct, within 18 months from the commencement of the order, but subject to limitations imposed by war conditions, the tramway from the dockyard gates to the new station and along the Queensferry Road up to the High Street of Dunfermline.

Edinburgh.—According to the burgh engineer, there are in the city 64 double-decked cars out of 200. With regard to the question of increasing the number, it was reported that a difficulty existed in respect to the low roofing of the existing tramway sheds, and that a considerable expense would be involved in raising the roofs to admit of any considerable additions to the number of double-decked cars. There was also a difficulty as regards haulage,

the present power being unequal to the strain of carrying on the the present power being unequal to the strain or carrying on the various routes of the city a very large proportion of double-decked cars. From inquiry it appeared that 20 to 25 of these cars could be added to the existing number with very little difficulty, and the Tramway Committee of the T.C. is to suggest to the company that another 25 such cars be put on the various routes.

The Tramway Committee is endeavouring to get a self-propelled car for experimental purposes, and is to gather information as to the part self-propelled traction might play in the city.

Halifax.—YEAR'S WORKING.—The income of the Corporation tramways for the year ended March 31st was £112,792, as compared with £109,650 in the preceding year. This is the largest figure since the system was opened. The profits amount to £17,539, or nearly £3,000 more than last year. The number of passengers carried was 20,707,071 carried was 20,707,071.

The Tramways Committee has decided to allow Belgian refugees to travel free of charge on the tramways, and special passes are being issued to these people.

Manchester.—The Special Corporation Committee appointed to deal with the question of the congested traffic in Manchester has held its first meeting and elected Ald. J. B. Wilson (chairman of the Improvements Committee) as chairman, and Ald. T. C. Abbott, deputy-chairman. It is understood that of the three voluminous reports prepared on the subject of traffic congestion by the Improvements, the Watch and the Tramways Committees, the report of the Tramways Committee will be first considered. The first business meeting of the new Committee will be subject of the tramways committee will be first business meeting of the new Committee.

first considered. The first business meeting of the new Committee will be held on April 13th.

A resolution is to come before the City Council that the Tramways Committee be recommended to allow special constables free rides on the tramcars when going to or returning from duty.

It is understood that some of the members of the Tramways Workers' Union are seeking permission to take a ballot on the question of the withdrawal of labour in consequence of the City Council's refusal to grant the increases in wages of 4s. 6d. and 3s. 6d. for carters and carriers and labourers.

Newcastle-upon-Tyne.—Reserve Fund.—At a meeting of the City Council on March 31st, it was stated that the reserve and renewals fund at March 31st, 1914, stood at £94,837, the estimated surplus on the year's working to March 31st, 1915, was £25,350, making a total of £119,687, from which is to be deducted expenditure sanctioned by the Council, leaving in the reserve and renewals fund on March 31st, 1915, the sum of £75,013. The estimated surplus for the year ending March 31st, 1916, was £31,400, but since the last report was issued the following additional estimated expenditure had had to be considered:—Army allowance for dependants (additional), £1,516; war bonus, £8,320; relief of rates, £18,000; additional cost of fuel, £5,000; reduced interest on investments, £1,000. There was, therefore, an estimated deficit of £2,436 on the year's working. Further, it would be necessary to expend from the reserve fund a minimum of £18,000 to keep the undertaking in a working condition, and with these deductions the reserve fund at the close of the year would only stand at £54,577. It would be impossible permanently to reduce the necessary expenditure on renewals in future years below only stand at £54,577. It would be impossible permanently to reduce the necessary expenditure on renewals in future years below an average of about £25,000 to £30,000 a year until the completion of the repayment of the loans. The Committee was of the opinion that the reduction of the reserve fund to so low a sum as £54,000 was unsafe, and that the contributions to the rates should be reduced in future years until the reserve fund was again built up to not less than £100,000. Alderman Rodgers, chairman of the Committee, in moving the adoption of the report, said the Committee must be allowed to accumulate an adequate reserve fund. He suggested that the allowances to dependants and the war bonus to employés should be deducted from the £18,000 which it had been proposed to allow towards the rates. After discussion the report was adopted. was adopted.

Portsmouth.—The Tramways Committee has decided against an application of the motormen and conductors for an immediate permanent rise of 5s. per week in wages.

Salford.—It is estimated that the profits of the department will be less by nearly £20,000 this year as compared with

Destination numbers on the cars have not proved satisfactory, and the Tramways Committee has decided to recommend that the previous method of indicating on the cars both the route and the destination be reverted to.

Venezuela.—A company has lately been formed to construct and work an electric tramway in the town of Valencia, The work of constructing the line is well in hand, while the ary current will be supplied from the plant of the existing electric light undertaking.

Wigan.—The Home Office communicated with the Corporation last week with reference to a proposal not to run the cars on Good Friday, and pointed out that the colliers had decided, at Lord Kitchener's request, to restrict their usual holiday and to work on the Friday, and that they would be seriously inconvenienced if the cars did not run. At a special meeting of the T.C. it was stated that the arrangements were made without knowing what the collieries intended to do, and it was decided to provide a service of cars. service of cars.

## TELEGRAPH and TELEPHONE NOTES.

Greece.—Direct communication has been established between Greece and Bulgaria and between Greece and Servia.

Journal Telegraphique.

High-Speed Cable-Cutting.—Speaking at Bristol on March 29th, the Postmaster-General said that within four hours of the outbreak of war we had severed every German cable that ran from Germany westwards or eastwards under the sea.

Japan.—Direct telegraphic traffic has been inaugurated between Russia and Japan, by way of the Korean port of Chonjin and Viadivostock.—Journal Telégraphique.

Postal Telegraphs and Telephones. — An account Postal Telegraphs and Telephones. — An account recently issued by the Post Office shows that the gross revenue of the British telegraph and telephone services for the year ended March 31st, 1914, was £10,468,399; the amount paid to cable companies, foreign countries, &c., was £878,316; telegram moneys refunded were £3,383; and the amount received in respect of royalties from the National Telephone Co., Ltd., and other licensees was £47,786; while services rendered to other public departments without remuneration were valued at £119,458. The total expenditure, including £1000,000 for interest and mark renowment of diture, including £1,000,000 for interest and part repayment of capital in respect of the purchase of the National Telephone Co.'s plant, was £9,821,978, leaving a debit balance of £68,034.

The amounts raised for telephone purposes to date made a total of £17,390,000, leaving a balance of £9,910,000 authorised but not raised. The excess of expenditure and interest on telegraph send telephone purposes.

over telegraph and telephone revenue for the year was £339,725. The capital expended on the trunk telephone system amounted to £7,549,963; on the exchange system and private wires, including £10,709,249 paid to the National Telephone Co., to £20,096,117; and on stores not allocated to £500,000, making a total of £28,146,080

£28,146,080. The expenditure for the year on the telegraphs was £3,509,010, exceeding the income by £390,794; including the interest on the purchase price of the telegraphs, the estimated pension liability, and provision for depreciation, the deficiency of revenue for the year was £1,211,742.

The expenditure on the telephone service was £3,385,796, and the revenue £6,175,372, leaving a balance of £2,789,576; after deducting interest on loans, pension liability, provision for depreciation, &c., the net surplus was £339,111. The working of the exchange system showed a net profit of £395,664, and of the trunk system a net loss of £156,553. The deficiency on the telegraphs in 1912-13 was £1,175,347, and the surplus on the telephones in that year was £303,343.

Submarine Telephones.—A demonstration was given in London last week of a submarine telephone by Captain Louis Sorche, an American inventor. The device enables a diver to maintain communication with the surface in spite of the noise in his helmet due to the roaring of the air supply and the pulsations of the number. of the pumps.

Telegrams in Code.—The Postmaster-General has given permission for the use of the authorised codes for telegrams to Brazil and French Guiana; the only South American country still excluded is Dutch Guiana.

Turkey.—It is reported that all English and French telephone employés in Constantinople have been replaced by Hungarians. The telephone service has been placed in the charge of an Austrian, and the telegraph service have been taken over by a Hungarian.

## CONTRACTS OPEN and CLOSED.

#### OPEN.

Aldershot.—April 20th. U.D.C. One 400-kw. D.C. turbine set, complete with surface condenser and circulating pumps, &c. One water-tube boiler with chain-grate stoker. See "Official Notices" March 26th.

May 4th. Steam and other pipework. Water-softening plant. See "Official Notices" March 26th.

Australia.—Melbourne.—April 19th. 13,560 yards of lead-covered cable, and 13 tons of bare hard-drawn copper cable, for the City Council. See "Official Notices" March 26th.

April 21st. 1 027,900 arc lamp carbons, for the Melbourne City Council. See "Official Notices" to-day.

May 19th. Electric signals and spare parts (Contract 28,591), track transformers (Contract 28,359), electric train stops (Contract 28,590), all for a period of five years. Particulars at Contractors' Room, Spencer Street.*

May 19th — Machine tools and equipment, and sprinkler, for the Melbourne, Brunswick and Coburg Tramways Trust. Specifications, &c, £2 2s. each, from the Engineer's office, Sydney Road, Coburg.

June 2nd. Electric lighting material for cars (Contract 28,187). Tender box, Railway Offices, Melbourne. Particulars at Contractors' Room, Spencer Street.* Deposit ½ per cent. of amount of tender.

tender.

June 2nd. Bogie trucks, wheels and axles for 10 cars of the St. Kilda-Brighton electric street railway (No. 28,621) for the Victorian Railway Commissioners.*

June 15th. Four mechanically-fired boilers, for the City Council. Specifications (£1 1s.) from the City Electrical Engineer.

QUEENSLAND.—June 1st (instead of March 16th). P.M.G. Switchboard for Warwick. See "Official Notices" March 26th.

Sydney.—May 31st. Three electric battery locomotives for new public abattoirs, Homebush, for the Public Works Department.

Specifications for the items marked * can be seen at the R. of T.

Specifications for the items marked * can be seen at the B. of T. Commercial Intelligence Branch in London.

engine generating set, motor-generator, balancer, underground cables. See "Official Notices" to-day.

Bradford.—April 17th. (A) 100 tramear trucks, (B) 200 motors, 200 controllers, 200 automatic circuit breakers, for the Tramway Department. Specifications (A and B) one guinea each, from Tramway Offices, 7, Hall Ings.

Brighton,—April 12th. Corporate denser. See "Official Notices" March 26th. Corporation.

Bristol.—April 14th. Incandescent electric lamps (from local firms or from firms in a position to supply from local stocks), for the Dooks Committee of the T.C., from May 1st to August 31st. Mr. T. A. Peace, Engineer.

Darlington.—April 20th. Corporation. 25-ton overhead traveller and economiser. See "Official Notices" to-day.

28th. Corporation. Centrifugal **Dundee.** — April circulating pumps, and 750 ft. of 42-in. and 30-in. cast-iron pipes. See "Official Notices" to-day.

Edinburgh.—Offers are wanted for upholding house

telephone and electric bell installations throughout the city properties. Superintendent of Works, City-Chambers.

Offers are also wanted to supply electrical material for interior wiring and jointing, and insulating material for electricity supply cables. Resident Electrical Engineer, Dewar Place.

Glasgow.—April 16th. Corporation. Cables, meters, carbons. See "Official Notices" to-day.
April 13th. Corporation. Six or twelve months' supply of V.I.R. cables, for the Tramways Department. Specifications from Mr. J. Dalrympie, General Manager, 46, Bath Street.

London.—Southwark.—April 14th. Cable and meters, for the Borough Council. See "Official Notices" April 2nd.

Mountain Ash, - April 26th. U.D.C. Sub-station building, E.H.T. underground cables, L.T. overhead lines and public lighting, E.H.T. switchgear, L.T. switchgear and transformers, for Aberoynon. See "Official Notices" to-day.

Manchester,—April 14th. Corporation. Three 1,250-K.V.A. static transformers. See "Official Notices" April 2nd.

Rhondda.—April 17th. U.D.C. Installation, 83 wiring points, 88 lighting points, at the Council Offices, Pentre. See "Official Notices" April 2nd.

Sheffield.—April 12th. Supply of motor-van (petrol or electric) to carry one ton, for the Corporation. Specification (10a.) from the Cleansing Superintendent, Town Hall.

## CLOSED.

Australia.—The Prahran and Malvern Tramways Trust has accepted the following contracts :-

Contract No. 61 (bo'ster and switch gear), Messrs. Noyes Bros. Pty., Ltd., Melbourne, £930.
Contract No. 62 (battery), Messrs. Elder, Smith & Co., Ltd., £2,817.

Batley.—The Corporation has accepted the following tenders :

Brush Electrical Engineering Co., Ltd.--Transformers. British Thomson-Houston Co., Ltd.--Switchgear.

Burton-on-Trent. - Two stokers and self-cleaning compressed-air furnaces have been ordered from Messrs. Ed. Bennis and Co., Ltd., for the Corporation electricity station. This is a repeat order.

Croydon.—The tender of Messrs. Callender's Cable and Construction Co. has been accepted by the Council for 12 months' supply of cables. The contract will provide for payment on a sliding scale based upon the market price of copper.

Dudley.—The Lighting Committee has accepted the tender of the Earl of Dudley, for a 12 months' supply of steam coal, at 17s, 6d, per ton.

Gillingham (Kent).—The T.C. has accepted the tender of Mesers. Spencer, Whatley, Ltd., for 300 tons of Nottingham slack (through about 2-in. screens), for the electricity works, at £1 3s. per ton; and if the whole of this cannot be supplied, to obtain the remainder from Mesers. Myers, Rose & Co., at £1 3s. 6d.

-The Electricity Committee has recommended Glasrow.for acceptance the offer of Mesers. John Bennie, Ltd., at £323, for the erection of an electric hoist in the premises of Messrs. Burton, Son & Sanders, Ltd., Kinning Park.

Grimsby.—The Public Lighting Committee of the Town Council has accepted the tender of Messrs. Johnson and Phillips, Ltd., at £296 10s., for a supply of cable.

-The B. of G. has accepted the tender of the Gath Electrical Engineering Co. for electrical fittings.

Huddersfield.—An order has been placed with Messrs. Elward Bennis & Co., Ltd., for four pairs of chain-grate stokers, each grate 4 ft. 3 in. by 12 ft. 4½ in. centres. for Surling water-tube boilers, for the Corporation electricity work .

Ilford.—The U.D.C. has made a contract with the British Thomson-Houston Co., Ltd., for 12 months' supply of their electricity meters.

Leyton.--The Education Committee has accepted the tender of Messrs, E. H. Grimshaw & Sons and Mr. H. H. Taylor for carrying out electric light repairs to the various schools in the district during the ensuing 12 months.

Liverpool.—The Electricity Committee proposes to accept the tender of Mesers. Babcock & Wilcox, Ltd., for three water-tube boilers and accessories, with coal and ash-handling plant, &c., for the Lister Drive power station; also the tender of Mesers. E Green & Son, Ltd., for three economisers and accessories. The Committee also proposes to accept the following tenders for appealing to the Theoremse Department in the Tenamera. annual supplies to the Tramways Department:

Lubricating oils and greases.—Vacuum Oil Co., Ltd.; Matthew, Wells and Co., Ltd.

And the following for similar supplies to the Electricity Department :-

Lubricating oils.—Vacuum Oil Co., Ltd.; Henry Wells Oil Co., Ltd. Electric fittings and suncries.—Bykes & Sugden, Ltd., 10 items; B.I. and Helsby Cables, Ltd., seven items; British E-certic Calibrated Fuse Co., one item; Simplex Conduits, Ltd., 11 items.

The tender of the Staveley Coal and Iron Co., Ltd., has been coepted for the supply of cast-iron circulating water pipes to the Lister Drive power station.

London.—WAR OFFICE —A contract for one 300-B.H P. Hick-Diesel engine has been placed with Messrs, Hick-Diesel Oil

Engines, Ltd.

L.C.C.—The Education Committee has accepted the tender of the
Lancachire Dynamo & Motor Co., Ltd., at \$36 10s., for a 5-H.P.
electric motor for driving the various machines at the Shoreditch Technical Institute.

Manchester.—The Education Committee has accepted the tender of Mesers, R. Saddon & Sons for electric lighting at the Alice Briggs Home.

The following tenders have been accepted by the Electricity

Bix superheaters.—Heenan & Froude, Ltd.
Two low-pressure droulating water pumps.—Gwynnes, Ltd.
Three reactance coils.—Siemens Bros. Dynamo Works, Ltd.
Cable.—Siemens Bros. & Co., Ltd.

The Sanitary Committee has accepted the tender of Messrs. Maitland & Co. for the electric lighting at the new ward pavilions at Moneall Hospital.

Meter Contracts. - Messrs. Ferranti, Ltd., have recently obtained contracts as follows for meters, the contract in each case being for the year ending March, 1916:

Bristol Corporation, c.c. meters.
Croydon Corporation, c.c. and A.c. prepayment meters.
Hammersmith Borough Council, A.c. prepayment meters.
Ilford District Council, c.c. meters.
Londonderry Corporation, c.c. meters.
Plymouth Corporation, A.c. meters.
Whitehaven Corporation, c.c. meters.

Nuneaton.—The tender of Mr. George Smith has been accepted by the Council for the supply, during the ensuing 12 months, of 2,000 tons Ansley Hall Smudge coal, at 6s. 9d. per ton, to the electricity works.

Richmond-on-Thames.—The Richmond, Heston and Isleworth Joint Hospital Board has accepted the tender of Mr. D. J. MacDonald, of Hounslow, for maintenance of the electrical installation at the hospital.

Salford.—Messrs. Siemens Bros. Dynamo Works, Ltd., have sgain secured the contract for the annual supply of Wotan, tantalum, and carbon-filament lamps to the Corporation Tramways Department.

The following tenders have been accepted for the purchase of scrap metal at the electricity station :

sap metal at the electricity station:—

8. Openshaw.—Old are lamps, approx. value of contract, £8i.

J. H. Broomhead.—Heavy cast-iron, light wrought-iron and heavy wrought
steel, £13 4s.

J. Livesey.—Copper, lead and light brass, £867 7s. 6d.

J. E. Peach & Bns.—Heavy brass, burnt cast-iron and subber, £48 10s.

T. Mitchell & Sons. Lid.—Motor-drivan boiler feed pump, £40.

8. Openshaw.—Steam feed-water heater, £5.

A. Learoyd.—Battery of accumulators, about 30 tons disused accumulator plates, connecting bars, &c., wood stillages, glass and porceiain insulators, battery booster and switchgear, and two balancers and switchgear, £706.

T. Mitchell & Sons.—Seven old electric motors, £49.

The following tenders have also been accepted: -Pendleton I onworks Co.—Steel work for car depôt extension, £1,480. Hadfield's, Ltd.—Axles, wheel tires and wheel centres, £1,186.

Walthamstow.—The U.D.C. has renewed its contract for the next 12 months for S.P. and D.P. 5 and 10-amp. tumbler switches, with Mesers. J. H. Tucker & Co.

Walton-on-Thames.—Messrs. R. Langston-Jones & Co. have secured the contract for the lighting and equipment for the new cinema for the Walton-on-Thames Cinema Co., Ltd., at \$251.

Watford.—The Electrical Apparatus Co. have withdrawn their previous tender for 200 meters, and the electrical engineer has been authorised to purchase the same number from the firm at the scheduled prices, to be taken when required during a period of two years. The tender of the British Westinghouse Co. has been accepted for the supply of 350 larger size meters at scheduled prices, to be supplied over a period of two years also.

The Electricity Committee has refused to grant a request from Messrs. Cory & Son, Ltd., for an increase in the price of coal under contract

contract.

#### FORTHCOMING EVENTS.

Association of Engineers-in-Charge.—Saturday, April 10th. Social and Dance.

Wednesday, April 14th. At 787 p.m. At 8t. B ide's Institute, Bride Lane, E.C. Paper on "Autogenous Welding," by Mr. L. M. Fox.

North of England Institute of Mining and Mechanical Engineers.— Maturday, April 10th. At 2 p.m. At Wood Memorial Hall, Newcastle. Discussion on various papers.

Royal Institution of Great Britain,—Monday, April 12th. At 5 p.m. At Albemarie Street, W. General Meeting.

Institution of Civil Engineers.—Tuesday, April 18th. At 8 pm. At Great George Street, S.W. Paper on "Impact Coefficients for Railway Girders," by Mr. C. W. Anderson.

Institution of Electrical Engineers.—Thursday, April 15th. At 8 p.m. At Victoria Embankment, W.C. Paper on "The Power Supply of the Central Mining—Rand Mines Group," by Mr. J. H. Rider.
(Manchester Local Section).—Tuesday, April 18 h. At 780 p.m. At Engineers' Club, 17, Albert Equare. Mr. Rider's paper as above.

(Scottish Local Section).—Tuesday, April 18th. At 8 p.m. At 207, Bath Street, Glasgyw. Annual General Meeting. Paper on "Power Plant Testing," by Mc. W. M. Selvey.

(Students' Section).—Wednesday, April 14th. At 7.30 p.m. At Victoria simbankmen, W.O. Paper on The Electric Drive of Rolling Mills," by Mr. J. M. Heslop.

(Birmingham Local Section).—Wednesday, April 14th. At 7.80 p m. At University, Edmund Street. Paper on "The Power Suppy of the Central Mining—Rand Mines Group," by Mr. J. H. Rider.

(Yorkshire Local Section).—Wednesday, April 14th. At 7 p m. At the Philosophical Hall, Leeds. Paper on "Good Lighting and its Immediate Effects from the Economic Standpoint," by Mr. V. H. Mackinson. Immediano, Mackinney.

Institution of Mechanical Engineers.—Friday, April 16th. At 8 p.m. At Beorey's Gate, B.W. Ordinary General Meeting.

#### NOTES.

Inquiries.—We are asked for information regarding "the ating of veneer plates by the se-called Hot Press System," for an heating of veneer plates by the se-called Hot Press System," for an important Canadian authority. Makers of the "Omnimeter" slide rule are asked for.

For Sale.—Messrs. P. Huddleston & Co. are instructed to sell by auction the cable, wire and fittings used for lighting the Liverpool Exhibition. Particulars are given in our advertisement pages to-day.

An Echo of the Building Strike.—In October, 1913, the London Education Committee accepted the tender of Messrs. Arthur Newman, Ltd., at £460, for installing electric light at the Middle Row School, Kensington. The school is being rebuilt in sections, and the first portion of the electrical work is now finished, the value being £213. Messrs. Newman have asked the Committee for an allowance in respect of the time which elapsed between the signing of the contract and the commencement of the work. The delay was caused owing to the strike in the building trade last year. The responsible Sub-Committee is of opinion that a payment of £6 2s. would be a fair and reasonable settlement of the claim, and has recommended the Committee accordingly.

The I.E.E. Benevolent Fund: An Appeal.—We commend to the sympathetic interest and generous support of our readers the appeal that has been issued by Sir John Snell, the President, on behalf of the Institution's Benevolent Fund. John says:

The Committee of Management have before them three urgent s which it is felt should be dealt with by the brother members

of those whose families are in need of help.

"There is one case of a member who died recently while on his way abroad to take up a very good position, whose widow and two children must be assisted by some charitable organisation. Another case is that of a member who was injured in an accident and is now mentally incomplete organization. accident and is now mentally incapable of earning any livelihood, and whose wife and four children are penniless. And there is yet a third case of three maiden ladies, the daughters of a deceased

and whose wife and four children are penniless. And there is yet a third case of three maiden ladies, the daughters of a deceased distinguished member, whose age and health make them incapable of earning anything towards their subsistence.

"In all these cases there are no relatives able to assist. The Committee, therefore, feel that each of these cases properly falls within the scope of the Benevolent Fund. There are in addition other cases of members and of families of members who are in receipt of assistance from the Fund, and it is anticipated that further deserving cases will in the near future come before the Committee. For an Institution of the size and importance of ours, a Benevolent Fund, which has been in existence for some 25 years, ought to have a larger accumulated capital than £4,640, and a larger income from investments than £175 per annum. During the year 1914 the annual subscriptions from members amounted to £87 only, and donations of single sums amounted to £93, that is, a total of £180, which is considerably less than could fairly be expected from an Institution of over 7,000 members. During this period of war, the positions and incomes of the majority of the members of the Institution have been only very slightly affected; and I venture to hope that a ready response will be made to my appeal to increase the resources of the Benevolent Fund, in order to enable the Committee to relieve the distressed and to assist the dependents of those of our members who have fallen by the way, as the amount at the disposal of the Committee is at present entirely insufficient to meet adequately the demands made upon it."

Fatality.—Langley.—At the inquest on the death of

Fatality.—LANGLEY.—At the inquest on the death of a labourer named Wilcox, aged 17 years, referred to in our last issue, evidence was given by Mr. John Legge, chief engineer of the Shropshire, Worcestershire and Staffordshire Electric Power Co., Ltd., to whom the wires belonged. He said that the War Office Ltd., to whom the wires belonged. He said that the War Office requested the company a fortnight ago to start immediately to get a supply of electricity to the site of the new Government works at Langley, which is near Albright & Wilson's works, to enable the men to work night and day. The nearest point from which they could get a supply was at Messrs. Albright & Wilson's works, and the firm permitted them to connect up from their transformer to the new works. The wires were carried on the top of a wall, the lowest wire being 10½ ft. from the ground, and they were considered to be perfectly safe. It was only a temporary arrangement, and, as soon as the underground cable was laid, the existing wires would be done away with. The voltage of one wire was 270, but if Wilcox caught hold of both wires he would probably receive a shock of about 500 volts. The jury returned a verdict of "Acotiontal death," and added the opinion that the wires were in a dangerous position. Though the wires were only there temporarily, they thought they should have been in some way protected. they thought they should have been in some way protected.

Institution and Lecture Notes.—Royal Institution. The following arrangements are announced:

Friday, May 7th, at 9 p.m., Prof. O. W. Richardson, "Electrons and Heat" (experimental).

" 28th, at 9 p.m., Sir John Jackson, "Engineering Problems of Mesopotamia and Euphrates Valley."

" June 4th, at 9 p.m., Prof. Sir E. Rutherford, "Radiations from Exploding Atoms."

Afternoon meetings (3 o'clock) :-

in General Physics."

Saturdays, May 1st and 8th, Prof. J. A. Fleming, "Photo-Electricity" (experimental).

Institution of Electrical Engineers.—At the meeting of the BIRMINGHAM LOCAL SECTION on Wednesday last a paper was read by Mr. W. C. Acfield on "Development of Main-Line Signalling on Railways," and a discussion followed. -At the meeting of the

on Railways, and a discussion ionowed.

Greenock Electrical Society.—At the last meeting a paper was read by Mr. L. Hogg on "Mains."

The following office-bearers were elected for next session:—Hon. president, Mr. Frank H. Whysall; president, Mr. W. B. Smith; vice-presidents, Messrs. Duncan Angus and Samuel James; secretary, Mr. H. G. Wright; treasurer, Mr. Wm. M Gibbon.

Appointments Vacant.—Engine driver-stoker (30s.), two switchboard attendants (20a.), jointer, meter fixer and reader (35s.), for Ilkley U.D.C.; car-shed superintendent (£200), for Bolton Tramways Department; switchboard attendant (25s.), for Kingston-upon-Hull Corporation; working permanent-way foreman (42s. 6d.), for Burton and Ashby-Light Railways, Particulars are given in our advertisement, pages are given in our advertisement pages,

How to Sell.—The Sales Managers' Association has arranged for to-night, Friday, at 7.30 p.m., a meeting to which "every British Business Man" is invited. There will be an address by Mr. C. Hamilton Wickes, H.M. Trade Commissioner in Canada, on "How to Market British Goods Abroad." Mr. Wickes holds that it is not in the quality of the goods that England is at a disadvantage in the industrial race for the world's markets, but in the methods adopted for making sales. We have no doubt that the meeting will prove a profitable one to all of our readers who can attend at this short notice. The announcement was only issued to us under date April 1st, and, of course, was not received by us until after the holidays. It is regrettable that an Association which aims at the improvement of our methods should not have issued as little longer notice of its arrangements—the eve of Good Friday was a particularly unfortunate date to choose for its circulation. We hope, however, that this reference to the matter will make an added impression upon the minds of our busy commercial readers, and will ensure a good sprinkling of electrical men among the audience at the King's Hall, Holborn Restaurant, to-night.

Fire at Dunston.—A fire occurred on April 5th at the Dunston electric power station of the Newcastle-on-Tyne Electric Supply Co., Ltd. An extension of the premises has recently been completed, and some new turbo-generators have been installed, completed, and some new turbo-generators have been installed, and it was in this section of the works that the outbreak occurred. For some time there were apprehensions of the fire seriously extending, but the work of the employés, aided by the military on duty in the neighbourhood, proved sufficient to limit the trouble. The damage done was said to be considerable, but fortunately the supply was not affected by the accident. One of the employés was rather seriously burned.

Engineer Volunteer Training Corps.—It has been suggested to the President of the Institution of Electrical Engineers, Sir John Snell, by General Sir O'Moore Creagh, V.O., Military Adviser to the Central Association of Volunteer Training Corps, that an Engineer Volunteer Corps should be raised from members of the engineering profession who are either above military age, or who, being of military age, are prevented by some good reason from serving in the Regular or Territorial Forces.

The objects of the corps would be to train men of military age to make them useful Boyal Engineers recruits if and when they are able to enlist, and to furnish engineer units to assist in the completion of the volunteer organisation. The units would be so constituted as to ensure that the maximum advantage would be taken of the specialised skill of their members.

or the specialised skill of their members.

Instruction and training will be given in military engineering, with special reference to field and fortress work (including telegraphs, telephones, searchlights, &c.), in addition to drill, musketry and other military operations proper to an engineer unit. Drills will be arranged so that each unit will receive instruction for at least two hours per week in the evening and on Saturday afternoons or Sundays. noons or Sundays.

The corps will be affiliated to the Central Association, and all the conditions contained in the War Office letter to Lord Desborough dated November 19th, 1914, will be observed. Members joining will be required to provide their own uniforms, and probably some part of the equipment.

The Institution has addressed a circular on these lines in the first instance to members residing in the London area. The question of forming similar corps for members residing outside this area will be considered at a later date.

Copper.—The European visible supply at the end of March was 29,056 tons, a decrease of 5,319 tons during the month. From Messrs. H. R. Merton's tabulated statistics we find that English supplies diminished by 698 tons during the same period. In dealing with the former figure (Enropean supplies), however, it will be noted that the figure given for French stocks at the end of February was based on the stock before the war, while that now issued is in accordance with official figures. The figures for enemy stocks are still, of course, conjectural. Figures of supplies from various sources show American arrivals in Europe largely in excess various sources show American arrivals in Europe largely in excess of any month since last July. The quantity received by England and France from Spain and Portugal during March, 1915, was well over the pre-war average, and the figure for supply from "other countries" was 7,178 tons, nearly half as much again as the pre-war average. Chile shipments were 10 per cent, under the pre-war average, and Australian about ‡ below. Total supplies very considerably exceed those for any month since the war started, and are 4,358 tons above the supplies for January, 1914.

#### OUR PERSONAL COLUMN.

The Editors invite electrical engineers, whether connected with the technical or the commercial side of the profession and industry, also electric tramway and railway officials, to keep readers of the ELECTBICAL REVIEW posted as to their movements.

Central Station Officials.—The Wimbledon T.C. has been recommended to appoint Mr. H. Oswald as an engineer-incharge at the electricity works at a salary of £104 a year, rising to £156 by annual increments of £13.

The marriage took place at Oldham on March 24th of MR. WM. CHAMBEBLAIN, one of the joint managers of the Oldham Corporation electricity department, and Miss Lilian Hood, daughter of the late Alderman John Hood, J.P., a former Mayor of Oldham.

MR. H. A. HISTED, of Croydon, has been appointed meter inspector at the Watford electricity works. Mr. T. W. Turner, assistant mains superintendent, has resigned his appointment.

MB. W. L. CHUBB, chief assistant at the Horsham electricity works, has resigned, having been appointed to a similar post at

Tramway Officials. - Mr. Frederick Taylor, carshed superintendent at Bolton, has resigned, and applications are to be invited for the vacancy, the salary offered being £200 per

-The staff of the offices of the British General.-Insulated & Helsby Cables, Ltd., Helsby, have presented a case of outlery, suitably inscribed, to MR. ERNEST BARKER, of Runcorn, a member of the office staff, upon the occasion of his marringe. The presentation was made by Mr. G. Seddon, the cashier.

MR. OSCAR C. WAYGOOD, of the transformer department of the British Westinghouse Works at Trafford Park, was married at Levenshulme Congregational Church at Easter, to Miss Lily Myers, only daughter of Mr. and Mrs. W. H. Linton, Victoria Park, Manchester.

MR. H. C. WALKER, chairman and joint managing director of Waygood-Otis, Ltd., lift and crane makers, on completing half-a-century's connection with the company, has been presented by the staff and employés with a grandfather clock and a morocoo bound album, containing the signatures of 600 employés, and the names of 250 members of the staff who have joined the services.

MR. JAMES G. LORRAIN has changed his address to 9, John Street, Adelphi, London, W.C.

Obituary.—Dr. H. Lewis Jones.—We deeply regret to learn of the death, which occurred on Sunday leat at his residence in Harley Street, of Dr. Henry Lewis Jones, M.A., M.D. Camb., F.R.C.P., London. For many years Dr. Lewis Jones had been one of our foremost authorities on medical electricity, indeed as long ago as February, 1893, he appeared among other experts on the side of the ELECTRICAL REVIEW in the litigation which followed upon its attacks on a certain extensive electric belt business. The upon its attacks on a certain extensive electric best business. The very responsible position which he occupied at St. Bartholomew's Hospital afforded him ample scops for the exercise of his specialised knowledge and experience, and gave him exceptional opportunity for adding thereto. For a lengthy period he was medical officer in charge of the electrical department at that Hospital, and we believe that he was responsible for the electrical department at the control of the electrical department at the second of the electrical department at the lectrical de equipment there being so efficient and complete. During the last year or two he had been connected with the same department in a less active capacity, as consulting medical officer. equipment there being so efficient and complete. During the last year or two he had been connected with the same department in a less active capacity, as consulting medical officer. His position as a recognised authority on electro-therapeutical and electro-medical subjects brought him into prominence as an author in a department which has too few authoritative exponents, and he occupied the presidential chair of the British Electro-Therapeutic Society in 1903 and 1904. He was an Associate of the Institution of Electrical Engineers, and in 1900 read a paper before that body "On the Applications of Electricity in Medical and Surgical Practice." Other writings of his within our recollection dealt with "Lethal Effects of Electrical Currents" (British Medical Journal, 1895); "Electrical Treatment of Infantile Paralysis" (Medical Society of London, 1894); and "The Duration of Discharges of Induction Colls." He was also the author of a well-known work on "Medical Electricity," based on the original work by the late Dr. Steavenson, of St. Bartholomew's, which went through many editions. Dr. H. Lewis Jones, who has passed away at the comparatively early age of 58, was a gentleman with whom it was a pleasure to have relations, and one who could not be known without being esteemed; his passing leaves a blank in an important department of Science, and he was an authority whom we could ill afford to lose.

SIE J. C. LAMB.—We regret to record that Sir John Cameron Lamb, formerly Second Secretary to the Post Office, died on March 30th at his residence at Hampstead. In the course of a lengthy account of his career appearing in the *Times*, it is stated that Sir John, who was born in 1845, entered the Post Office in 1864, and he retired in 1905, after more than 40 years' service. He at first served in the Receiver and Accountant-General's Department, but in 1870 he was selected with others to assist in negotiations for the in 1870 he was selected with others to assist in negotiations for the acquisition of the inland telegraphs, which up to that date had been entirely in the hands of private companies. Mr. Lamb took a prominent part in the organisation of the acquired telegraph systems and their extension to meet the growing requirements of the public. In 1888 he carried out most of the arrangements in connection with the introduction of 6d. telegrams. A rapid development in the international telegraph system has taken place since 1870, and many questions affecting the control of the cables laid by British companies and the relations with foreign telegraph administrations were continually arising for settlement, and Mr. Lamb took a large part in the arrangement of these matters. In 1886 he was one of three delegates appointed by the Secretary of State for Foreign Affairs to attend an international conference in State for Foreign Affairs to attend an international conference in Paris on the protection of submarine cables, and he subsequently served as a member of the Commission appointed to examine the laws of the various countries bearing on the subject. In 1884 and again in 1888 Mr. Lamb attended conferences with the officials of various telegraph administrations, and negotiated agreements for the international cables. These the joint acquisition and working of the Continental cables. These arrangements, which were carried into effect in 1889, resulted in the purchase of the cables from the Submarine Telegraph Co. Mr. Lamb took part in three international telegraph conferences—in 1890 in Paris, in 1896 at Buda-Peeth, and in 1903 in London. At the Paris and Buda-Pest conferences he was the senior British delegate,

and at the London conference was elected president. In 1903 he was the senior British delegate at the first International Conference on Wireless Telegraphy held in Berlin. In 1895 Mr. Lamb negotiated the purchase of the telephone trunk lines connecting the various centres, and organised a State system extending to the principal towns in England, Scotland and Ireland, and also to Paris. Mr. Lamb was appointed third secretary of the Post Office in 1896, and in the following year became second secretary. He took a leading part in discussions upon the policy which should govern the relations of the Post Office to the National Telephone Co. and the municipalities in connection with the telephone service, and gave evidence before a Select Committee of the House of vice, and gave evidence before a Select Committee of the House of Commons in 1898. From 1892 to 1897 he served as a member of the Royal Commission appointed to consider the establishment of electrical communication with lighthouses and light-ships. He received the C.M.G. in 1890, the C.B. in 1895, and a knighthood on

MR. B. TUKE.—The death occurred on April 4th, at the age of 57 years, of Mr. Richard Tuke, Chief Superintendent of Telegraphs at the Leeds Post Office. He joined the telegraph service in Leeds in 1673, and passed through all the successive grades to the post of chief superintendent, to which position he was appointed only last year. His death was quite unexpected, for he attended to his duties as recently as March 27th.

#### CITY NOTES.

#### Cork Electric Tramways and Lighting Co., Ltd.

The directors' report for 1914 states that the revenue was £61,604, and the expenses were £37,958. Including £1,352 brought forward, there remains £24,998, less interest on deben-Including £1.352 brought forward, there remains £24,998, less interest on debentures £4,600, leaving a balance of £20,398. Of this amount dividends on the 5 per cent. cum. pref. shares absorbed £6,163, £6,500 had been added to reserve for depreciation and renewals, £1,804 had been written off several items, a 3 per cent, dividend on the ordinary shares requires £3,450, and £2,480 is to be carried forward. The lighting and power business again shows satisfactory progress, agreements for 161 connections being concluded during the year. The additional connections represent a total gain of 467 kw. as against 212 kw. in 1913. The revenue amounted to £61,604, an increase of £1,469. The lighting and power revenue was £1,509 in connections represent a total gain of 401 kW. as against Lik KW. in 1913. The revenue amounted to £61,604, an increase of £1,469. The lighting and power revenue was £1,509 in excess of the previous year and the traction revenue £140 less, the decrease being mainly due to the war. The other revenue items show an increase of £100. The expenses amounted to £37,958, as compared with £37,524 for the previous year. There was a reduction of £1,315 in traction and lighting expenses regardly due to lower maintenance charges for permanence of £100 in the contract of the contraction of £1,315 in traction and lighting expenses regardly due to lower maintenance charges for permanence. penses, mainly due to lower maintenance charges for permanent way and cables. Power expenses, on the other hand, were increased to the extent of £1,700, due partly to the increased output and partly to heavier maintenance charges for the plant. The general expenses show a small reduction. The capital expenditure during the year, amounting to £2,500, has been mainly for house services and additional plant for the power station. To meet the increasing demand for lighting and power the directors have ordered a 1,000 kw. direct-current geared Curtis turbine. In view of the substantial increase in the cost of coal and other materials, also wages, dues to the war, the directors may have to consider the question of increasing the charges for electricity

The annual meeting was held yesterday.

Clyde Valley Electrical Power Co.—The report states (says the Financier) that, after payment of the preference share dividend and adjusting interest and transferring £12,500 to contingency fund for depreciation, &c, there remains £33,826. The directors recommend that £3,290 be transferred to special reserve, £10,000 applied in writing down cost of accounts, and £9,000 provided for the dividend on the preference shares to April 30th, leaving £11,535 to be carried forward.

Lymington Electric Light and Power Co., Ltd.-The result of trading during 1914, including £769 brought forward, shows a profit to the credit of the net revenue account of £2,668, and after paying interest on debentures, amounting to £450, there is a balance of £2,218; £1,000 is to be placed to reserve account, and a dividend at the rate of 5 per cent. per annum paid on the preference shares, amounting to £321, leaving £897 to be carried forward. During the year the company have invested £1,000 in Colonial Government Stocks.

Oriental Telephone and Electric Co., Ltd.—Subject to audit, the directors recommend the following dividends:—At the rate of 6 per cent. per annum on the preference shares for the half-year ended December 31st last, less income-tax; a final dividend of 6 per cent. on the ordinary shares issued, free of incometax, making a total of 10 per cent. for the year. The share transfer books will be closed from April 15th to 28th.

#### Brush Electrical Engineering Co., Ltd.

THE annual meeting was held at 1, Kingsway, W.C., on March 20th. Mr. E. Garcke, who presided, congratulated the shareholders on the improved position of the company. The improvement which he was able to report at the last general meeting was fully maintained during the past year, notwithstanding the difficulties and the dislocation of business caused by the way and the accounts showed that the company was standing the difficulties and the dislocation of business caused by the war, and the accounts showed that the company was again getting into a thoroughly sound position. Now that they had turned the corner and were making profits, he was able to confess that there were times during the last five or six years when the directors were very nearly despairing of being able to pull the company out of its difficulties, but there were two factors which sustained them, and which explained the success they had achieved. In the first place, they appreciated very much the patience shown by the stockholders and the confidence which they gave the directors, and in the second place the extraordinary efforts made by the managing director and the whole of the staff in their struggle against adversity. place the extraordinary efforts made by the managing director and the whole of the staff in their struggle against adversity, were such as inspired everyone with confidence in their ultimate success. During the past year they had completed the re-organisation of the share capital account, and the balance sheet was now free from all items of doubtful validity, and showed a balance of undivided profits which was not only substantial but real. They would be perfectly justified in declaring a moderate dividend on the ordinary stock, but although the directors would have derived much pleasure in paying a dividend, they thought and felt that war time was not although the directors would have derived much pleasure in paying a dividend, they thought and felt that war time was not a time for a company which had just emerged from a long period of depression to begin the payment of dividends. After the experience they had gained, therefore, they considered that, when the company resumed payment of dividends, it must be with the conviction that in the absence of altogether unforceseable calamities they would be able to pay dividends regularly later. The uncertainty of war conditions did not provide a reliable basis for any such conviction, and, therefore, they must reluctantly ask the holders of the ordinary stock to exercise a little longer that high quality of patience which they had practised so long with such beneficent effects upon the fortunes of the company. They paid, of course, for the past year, as they had always done, the full interest upon the whole of the debenture stocks, and they also paid a further 4 per cent, for the year on the 6 per cent, second prior lie debenture stock, making 10 per cent, for the year. After dealing with the accounts, the Chairman said that with regard to their operations generally, they had naturally suffered by the falling away of orders during the latter part of the year under review, and they had also been, and were still, handicapped by the shortage of labour and the difficulty of getting raw materials. The latter were adverse factors which, he was afraid, were likely to continue during the war, and might even increase. On the declaration of war everyone's first instinct was to at once begin husbanding resources, and their order sheets for the first two or three months immediately following the declaration of war did not make satisfactory reading. However, as confidence was re-established, an improvement took place, and this was assisted by the Government orders which the company was able to secure. This improvement had continued, and they had no cause to compaying a dividend, they thought and felt that war time was not provement took place, and this was assisted by the Government orders which the company was able to secure. This improvement had continued, and they had no cause to complain of the volume of business obtained since the beginning of the current year. They took early steps to not their manufacturing facilities at the disposal of the Government, and at the present time a large proportion of their output was for material for Government service. They were building not only turbo-generating plant and other engineering and electrical machinery for this duty, but had also undertaken the construction of aeronlanes to standard and improved designs, and they hoped shortly to have the special department they had organised for this work in full swing. In common with other engineering firms, they had granted a substantial all-round increase of wages to their workmen, and they were now faced with a demand for a special war bonus. They fully recognised that the cost of living had gone up, and that the men were that the cost of living had gone up, and that the men were entitled to more when more was being earned, but these continued advances of wages were liable to hit the firms engaged in the beavy section of the electrical engineering industry in the heavy section of the electrical engineering industry very much, because their contracts were of a nature that often extended over many months, and as they had to engage to deliver their products at a fixed price, it was not possible to obtain relief in respect of higher wages paid as regarded work already in hand. He hoped the men's representatives would admit that these advances could not be permanent, for in the nature of things the present conditions could not be peradmit that these advances could not be nermanent. For in the nature of things the present conditions could not be nermanent. At their meeting last very he told them of the success of the new steam turbine they had taken un. He referred to the Liungstrom turbine. He was glad to report that the experience they had since gained in every way justified their action in securing manufacturing rights for this invention. It had fully realised their expectations, and was now firmly established as the most economical turbine on the market while at the same time its reliability in operation under severe conditions had been completely confirmed. The remarkable results obtained in the way of steam economy annealed strongly to all owners of electric newer undertakings in situations where fuel was costly, and the orders in hand and in prospect had compelled the directors to face the problem of providing means for turning out the turbine, with its appliary equipment of generators, condensers and numbs, on a larger scale, and with labour-saving high-speed tools. Machine tools of this class were already on order, and some of them would have been installed before now if it were not for the fact that the tool makers were all very busy in turning out machinery for munitions of war. The progress made in exploiting the Ljungstrom turbine, satisfactory though it was, would have been still more marked in more normal times, as many municipalities, who were their principal customers for this class of plant, were holding up projected extensions in their powerhouses in consequence of the present difficulty of obtaining the necessary Government sanction for expenditure. At this moment they had a considerable amount of business held up on this account, and he looked for a large demand for the turbine as soon as the existing restrictions were removed. On their rolling stock side the shops had, on the whole, been kept well employed. They were building a large number of cars for the L.C.C. tramways, and were finishing a line of steel carriages embodying many special and improved features for the Central London Railway. They were adapting and extending some of the workshops for the manufacture of aeroplanes, for which they had already important orders in hand. To meet the capital expenditure necessitated by these developments, they proposed, as soon as they required the money, and subject, of course, to the approval of the Treasury, to issue the balance of their prior lien participating second debenture stock. The exact amount of this stock available was £48,899, and it carried fixed interest at the rate of 6 per cent. per annum, and was entitled to a further 4 per cent. out of the net profits of the company available for dividend in any year. The Chairman added that over 20 per cent. of the company's men, including officers, had joined the Army and Navy, and the directors had joined in a scheme which had been propounded by the British Electrical Federation for assisting the dependents of the men.

Mr. B. S. BROADHURST seconded the motion.

An amendment that the meeting should stand adjourned or the purpose of enabling the directors to reconsider the

accounts with a view to the payment of a small dividend on the ordinary shares was not seconded, and the motion for the adoption of the report was agreed to unanimously.

# British Westinghouse Electric and Manufacturing Co., Ltd.

The 15th annual general meeting was held on March 29th at Hamilton House, Victoria Embankment, Mr. J. Annan Bryce, M.P., presiding. In moving the adoption of the report, the Chairman, after referring at some length to the balance sheet, said that the net profit was about £45,000 more than that of 1913. That excellent result was caused mainly by increased efficiency. They possessed a very able management and a first-rate staff, built up during years by the managing director, and actuated from top to bottom by a spirit of devotion to its work. While he congratulated them on the result of the year's working, he must utter a word of caution. In some of the newspaper he congratulated them on the result of the year's working, he must utter a word of caution. In some of the newspaper comments on the accounts it was said that they seemed to have benefited by the war because they had earned a much larger profit. Although five months of war came within the period covered by the accounts, any such deduction was entirely wide of the truth. The profit of the year was almost entirely, if not entirely, derived from contracts entered into before the war; most of it, indeed, on contracts nade in 1913. As a matter of fact, they had already suffered, and were likely to suffer still more, from the war, though its iniurious effects were not apparent in the accounts of 1914. The net profit was just sufficient, if they had divided right up to the hilt, to have allowed a distribution of 15 per cent, on the preference capital. But in the opinion of the board it was much wiser, with the present uncertain outlook, to continue the policy of strengthening their resources by building up reserves. They had, accordingly, added £50,000 to general reserves, written £25,000 off goodwill, and carried forward a rather larger sum than last year. When they met last year he told them that up till that date the orders taken during the first three months of the year were about the same as for the corresponding period of 1913, but that there were signs of a slackening in trade. During the succeeding four months, the slackening hecame of the year were about the same as for the corresponding period of 1913, but that there were signs of a slackening in trade. During the succeeding four months, the slackening became marked, and by the end of July their fresh orders for the year were 27 per cent, behind those during the first seven months of 1913. The comparison, however, was not quite fair to 1914, as in that period of 1913 they had taken a very large electrification order from the London & South Western Railway Co. The cation order from the London & South Western Railway Co. The sudden outbreak of war in the beginning of August perturbed their industry, as it did all others. Happily, they were in a strong financial position and had no anxieties on that score, but trade being for the time paralysed it appeared necessary to shorten sail. Two alternatives presented themselves: either to reduce the staff, or to ask it to accept short time or reduced pay as the case might be. The former course they were reluctant to adopt, not only for their staff's sake, but for their own. They had a splendid personnel which had taken years to build up, and once dispersed it would have been difficult to reconstruct, so they took the other course. The staff without a paurmur at once most loyally agreed. The clerical staff accepted reduced pay but continued to work full time, while struct, so they took the other course. The stair without a bournur at once most loyally agreed. The clerical staff accepted reduced pay but continued to work full time, while the manual labour accepted short time. Things having settled down, a return to normal conditions of work and pay was made in a few weeks. As the autumn went on, the stonpage of business with Germany began to make itself felt and orders were given to them in replacement of cancelled German contracts. At the same time the War Office and

Admiralty, to whom they had offered their services at the outbreak of war, placed with them orders for various goods, and they also took sub-contracts from other firms to assist and they also took sub-contracts from other firms to assist their deliveries. Owing to those causes the volume of orders, which at the end of July had been 27 per cent. behind, finished up at December 31st only 17 per cent. behind that of 1913. So far, therefore, as mere volume of business was concerned, the war had rather improved their position. The mere volume of orders taken in any year, or their character, did not affect in any considerable degree the profits of that year, but had an important effect on subsequent periods. The diminution of 17 per cent. in the orders of 1914 was therefore in itself serious, and had a still more serious aspect when they came to consider the conditions under which they were they came to consider the conditions under which they were being executed. In this connection the effects of the war would be found to be very injurious indeed. The active recruiting of the autumn, and the increasing demand for war recruiting of the autumn, and the increasing demand for war supplies of every kind, rapidly caused a shortage of labour, especially of skilled labour, which towards the end of the year became acute. Lancashire responded nobly to the call of patriotism, and their staff did not lag behind. By the end of 1914 about one-third of their men had joined the Colours, and they replaced them with great difficulty. But the labour difficulty was not the only evil effect due to the war. The Government work which, for various reasons, they thought it wise to take, was not in itself profitable, the material being furnished to them and their remuneration being based in most cases merely upon a small percentage material being furnished to them and their remuneration being based in most cases merely upon a small percentage on wages. There had been a rise of 10 to 12 per cent, in the cost of every material they used, while the enormous rise in freights had seriously affected the results of their contracts for foreign and export work, as well as making further business far more difficult. They would, of course, endeavour to meet present conditions, not only by increasing prices where possible, but by increased efficiency, and, apart from war conditions, he thought their prospects were favourable. Even now there was a fair amount of business offering, and when the war was over there ought to be a chance of securing a good proportion of the business heretofore done in Germany, as there was likely for some time after the war to be in many countries a prejudice against her, even if her industry was not so disorganised as to interfere with her supplying her many countries a prejudice against her, even if her industry was not so disorganised as to interfere with her supplying her former proportion of the trade. The report alluded to their acquisition of their American friends' interests in the French and Italian Westinghouse companies. He should explain that their interest in the Italian company was an indirect one through the French company, which held a large majority of the shares of the Italian company. Their friends, after the experience of a number of years, during which neither of those companies had paid a dividend, had come to the conclusion that it was impossible to exercise a proper supervision from the other side of the Atlantic, and in pursuance of this policy they had already transferred their interests in Russia to a local company. They expressed to this company their willingness to code to it their French interests. They offered what appeared to be favourable terms, trusting from what they had seen of this company's operations that it would be able to make the business both in France and Italy profitable, they had seen of this company's operations that it would be able to make the business both in France and Italy profitable, in which case they would get a return through their large holding in the British company. The French company had a capital of £560,000, divided into 10,000,000 francs cumulative preference shares, of which the American interests owned 8,745,000, and 4,000,000 francs ordinary shares, of which they owned 2,876,700, these holdings in both classes amounting to 83 per cent. of the whole. The Italian company had a capital of £160,000, of which the French company owned 73 per cent. Their American friends had sold them their interest in the French company in exchange for their holdings in the Clyde Valley Electrical Power Co. and the Traction & Power Securities Co., Ltd., at the prices at which Traction & Power Securities Co., Ltd., at the prices at which they stood on their books on December 31st, 1914, viz., £160,127. The transaction thus amounted to their buying the American interests in the preference shares above at about half their face value and getting their ordinary shares thrown in for nothing. They considered that the bargain was a good one for them. They had of late years had ample opportunity of seeing the working both of the French and Italian companies, and formed the opinion that their want of success hitherto had been due to conditions which they and their American friends were confident that they would be able to improve. By bringing the work of the two companies' engineering and selling establishments into co-ordination with their own, they would be able to avoid over-lapping in both departments, thus saving heavy expenses in development and other work. Both companies had factories well adapted for American interests in the preference shares above at about other work. Both companies had factories well adapted for certain work, and by concentrating at Manchester other work which they had been attempting to do they would be able to add to the volume of their own standard manufactures. At the present moment ordinary electrical manufacture was completely suspended in France, and the works there were entirely taken up with Government contracts for municipal which wielded a fair return; but when the work was well as the work when the work was well as the work when the work was well as the work when the work was well as the work when the work was well as the work when the work was well as the work when the work was well as the work when the work was well as the work when the work was well as the work when the work was well as the work when the work when the work when the work was well as the work when the work was well as the work when the work when the work when the work when the work when the work when the work when the work when the work when the work when the work when the work when the work when the work when the work when the work when the work when the work when the work when the work when the work when the work when the work when the work when the work when the work when the work when the work when the work when the work when the work when the work when the work when the work when the work when the work when the work when the work when the work when the work when the work when the work when the work when the work when the work when the work when the work when the work when the work when the work when the work when the work when the work when the work when the work when the work when the work when the work when the work when the work when the work when the work when the work when the work when the work when the work when the work when the work when the work when the work when the work when the work when the work when the work when the work when the work when the work when the work when the work when the work when the work when the work when the work when the work when the work when the work when the work when the work when the work when the work when the work when the work when the work when the work when the work when the work when the work when the work when the work when the work when the entirely taken un with Government contracts for munitions of war, which yielded a fair return; but when the war was over they would have a good chance of securing, in addition to their previous business, a portion of the large amount of electrical work hitherto supplied to France from Germany. The Italian company was busy with contracts for electric locomotives for the Italian Government, a class of business for which it had obtained an excellent reputation, and in Italy, too, there should be good prospects of obtaining a con-

siderable share of the business hitherto done with Germany in ordinary electrical work. Both companies were financially sound, though the Italian company suffered from an insound, though the Italian company suffered from an inadequate working capital, a deficiency which they believed
could be supplied at the close of the war by the French company from its own resources without making any demands
upon this company. This company's control of the French
company would give an important advantage in another way.
Through it this company would obtain an entry into Switzerland, Belgium, Spain, Portugal and their respective colonies,
business in which the French company had not developed.
With regard to prospects of business generally after the war,
they would not expect him to prophesy. As they knew it they would not expect him to prophesy. As they knew, it was expected by most people that a great depression in trade would follow the close of the war. "The expenditure of the present belligerents alone cannot, if the war lasts only eighteen months, fall much short of 5,000 millions of pounds. Add to this the expenditures by neutrals due to the war, say, worther 100 millions the depression of property and the description of property and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the sa Add to this the expenditures by neutrals due to the war, say, another 100 millions; the destruction of property certainly at least another 1,000 millions; the loss by non-creation of wealth from the labour of at least 12 millions of fighting men for eighteen months, at the low estimate of £50 per man, arother 600 millions; and the permanent loss by non-creation of wealth, say, for four years from the death or disablement of, say, four millions of fighting men, another 1,000 millions, you get the appalling total of capital loss of; say, 8,000 millions of pounds. And this vast sum does not include anything for the diminished production of wealth caused by the diversion of immense bodies of labour, not only in the belligerent sion of immense bodies of labour, not only in the belligerent but in many neutral countries, from the production of wealth to the production of unproductive war supplies, or for the consequent disorganisation of industry. Nor does it include anything for the incalculable diminution in production which anything for the incalculable diminution in production which must follow from the death or enfeeblement by famine and disease of huge numbers of human beings in the war areas." It would certainly take the world a generation to recover from the effects of the war, and its purchasing power must be vastly lessened in the immediate future. But it did not follow that all industries would be equally affected. Those which were, like their own, concerned with the provision of more economical means of production and transport might even benefit, especially considering that so extensive a destruction of the older types of mechanical production might furnish even benefit, especially considering that so extensive a destruction of the older types of mechanical production might furnish an opportunity of reconstruction on modern lines. Up to the end of 1914, 1,366, or about one-third, of their staff in Manchester had joined the Army, and the number had risen on March 8th to about 1,500. Men had also joined from their Lendon and district offices, and from their Russian and South African offices. Many of them were already at the front and had suffered wounds and death. All honour to the gallant fellows who were braving for their country's sake the horrors of winter warfare in the trenches. And their gratitude was due not only to those with the Colours, but to those who had remained behind to perform the no less honourable task of maintaining the country's industries. "The fight is not at the front alone." At the beginning of September a fund was formed to provide relief for the dependents of men joining the Army. To this fund the company contributed £100 weekly, and to it the staff had up till March 6th contributed £3,550. A system of regular daily instruction for apprentices had been started in a lecture-room fitted up for the purpose. Lectures were given by members of the staff some of them formers. The sign methelong them. instruction for apprentices and been started in a lecture-room fitted up for the purpose. Lectures were given by members of the staff, some of them foremen. Tutorial work by foremen broadened the instructor's own view and tended to create in him a greater interest in the progress and welfare of the boys. The school was open on the average 7½ hours every day, and 271 apprentices had received instruction. He was sure they would agree that this school was performing a most sure they would agree that this school was performing a most

sure they would agree that this school was performing a most valuable work, and the thanks of the company were due to those who so unselfishly carried it on.

Mr. E. A. GOULDING, M.P., seconded the motion.

Mr. H. W. Birks said that he thought the shareholders looked forward to the future with even greater confidence than the Chairman would seem to by the tone of his speech. The board had done so well in former years that he thought the report encouraged them to hope that their prosperity would continue in the future. He thought something might be done in the way of legislation by which companies like their own should not have to compete with foreigners when local authorities and the Government were giving out their contracts.

contracts.

The Chairman, in reply, said he did not take a pessimistic view of the future for, as he had said, he thought that many companies were likely to be a great deal worse off than themselves. He thought, however, they must not expect that the accounts for the current year, and probably those for 1916, would be as good as those now before them. The labour difficulty was a very serious one, and he thought they had a great deal to thank the trade union leaders for in the way in which they had managed affairs during this trying time. With regard to legislation on the subject of contracts going abroad, there Mr. Birks raised the whole question of Free Trade or Protection, and he felt sure there was very likelikelihood of any legislation on the point at the moment. He must say that since the war, owing to the dishonourable pretensions of Germany, he took quite a different view on that particular question to that which he previously held—not that he thought we ought to have Protection; but he would expect that the attitude of persons in this country towards Germans would be different from what it was before the war.

detested the Prussians, but it must not be forgotten that the reason they had been so successful in capturing trade both in this country and in our Colonies was because they were willthis country and in our Colonies was because they were willing to provide what the people wanted, whereas English manufacturers were in many instances too slow to adapt themselves to new conditions. Generally speaking, Government departments had given a preference to English contracts where possible, and he believed that when the war was over that attitude would be very much accentuated here, and especially in France and Russia.

The report was adopted.

#### Urban Electric Supply Co., Ltd.

MR. P. D. TUCKETT (Chairman) presided on March 31st, at Salisbury House, E.C., at the annual meeting. In moving the adoption of the report, the CHAIRMAN said that having regard to the exceptional conditions under which the business was conducted during the latter half of the year they might consumitate themselves on being able to present so satisfactory as gratulate themselves on being able to present so satisfactory a report. Their profits were larger by some £4,000, out of which they were able to pay an additional 1 per cent. dividend on the preference shares, after meeting the increased interest and redemption charges, and after appropriating £10,904 to reserve redemption charges, and after appropriating £10,904 to reserve for depreciation. A year ago the corresponding appropriation was £12,000, so that superficially they appeared to be now making a smaller reserve provision, but this was not really the case. The Cornwall company earned in respect of the past year a profit of £17,325, of which only £12,162 was brought into their profit and loss account. For 1912 and 1913 a portion of the reserve provision made in their accounts was earnered to the Cornwall company, whereas on this occasion tion of the reserve provision made in their accounts was earmarked to the Cornwall company, whereas on this occasion that company had made an independent reserve provision for the year of £4,000, so that if they added this £4,000 to the £10,904, which they proposed to set aside, the total provision made for depreciation this year was nearly £15,000, as compared with £12,000 a year ago. The capital expenditure for the year was £35,000, and this was met by the sale of £24,524 debenture stock and by utilising the reserve provision appropriated from revenue, the "amount due to contractors" being reduced by about £1,300. During the current year capital expenditure was likely to show a further reduction compared with recent years, although they might still have to spend something not far short of £30,000, for, in spite of the war, it was neither desirable nor possible entirely to shut off all capital expenditure. They were proposing shortly to make capital expenditure. They were proposing shortly to make an issue of debenture stock of the Cornwall Power Co. It would be a 5 per cent. stock, of a particularly well secured would be a 5 per cent. stock, of a particularly well secured character, inasmuch as a statutory company could only issue debenture stock to the extent of one-third of its paid-up capital, i.e., to the extent of one-fourth of its capital assets. The company was doing remarkably well, having already in its third year of working earned a return in excess of 8 per cent. on its entire capital, or sufficient to cover the debenture interest more than five times over, and there was every promise of its continuing to make equally satisfactory progress as the business further developed. The proceeds of the issue would be applied in part to repaying the Urban company a portion of the advance which it had made to the Cornwall Co. The issue would probably require the Treasury's approval, and they had not yet secured this, but they did not anticipate that they would have any difficulty in doing so. Reverting to the balance sheet, the various revenue reserves, which amounted to less than £10,000 in 1911, when they reduced their capital, now stood at £73,445, before crediting the provision of £10,904, to less than £10,000 in 1911, when they reduced their capital, now stood at £73,445, before crediting the provision of £10,904, which they proposed to set aside in respect of the past year, and without taking into account £8,000 standing to the credit of the Cornwall company's reserve for depreciation. On the other hand, the capital reserve had been reduced by a further £9,394 in the process of giving effect to the object for which it was created, and following the same procedure as in previous years. They had connected during the year the equivalent of 76,200 33-watt lamps, or rather less than in the previous two years. Still, it was a most substantial and satisfactory addition of 10 per cent. and it was entirely owing to the war that years. Still, it was a most substantial and satisfactory addition of 10 per cent., and it was entirely owing to the war that the previous records were not exceeded, for the connections for the first half-year were considerably larger than those for the corresponding period of the previous year. As it was, the power connections exceeded those for 1913 by the equivalent of 3.704 lamps, the reduction being in the lighting connections, which were less by the equivalent of 10.328 lamps. The lighting connections represented an increase of 5 per cent., and the rower connections an increase of 16 per cent, on the previous ing connections represented an increase of 5 per cent, and the power connections an increase of 16 per cent, on the previous respective totals. The output for the past year increased by 2.000.571 units, from 22.034.983 to 24,005.554, an increase of rather more than 9 per cent, the lighting units having increased 6 per cent, and the power units 10 per cent. Of this output, the Cornwall company's properties, even of the content of the company's properties, even of the content of the company of the content of the content of the content of the content of the content of the content of the content of the content of the content of the content of the content of the content of the content of the content of the content of the content of the content of the content of the content of the content of the content of the content of the content of the content of the content of the content of the content of the content of the content of the content of the content of the content of the content of the content of the content of the content of the content of the content of the content of the content of the content of the content of the content of the content of the content of the content of the content of the content of the content of the content of the content of the content of the content of the content of the content of the content of the content of the content of the content of the content of the content of the content of the content of the content of the content of the content of the content of the content of the content of the content of the content of the content of the content of the content of the content of the content of the content of the content of the content of the content of the content of the content of the content of the content of the content of the content of the content of the content of the content of the content of the content of the content of the content of the content of the content of the content of the content of the content of the content of the content of the content of the content of the content of the increased 6 per cent., and the power units 10 per cent. Of this output, the Cornwall company's proportion exceeded 16,000,000 units, and was sold at an average profit of .253d., or a trille over a farthing per unit, whilst the remainder realised an average profit of 1.104d, per unit. It was interest-ing to compare these rates of profit with the estimated profit of 3d, per unit on which the original prospectus figures were based in 1901. They could not have a better illustration of the enormous changes which had taken place in the character and conditions of the business, owing to the introduction of and conditions of the business, owing to the introduction of the incandescent gas mantle, the creation of a heating load, and the enormous and altogether unforeseen development of

the power load, for it was to these developments and to the increased efficiency of the plant rather than to any marked inadequacy of price that the difference in the figures were attributable. In illustration of the profitable character of power load at even so comparatively small a profit as a farthing per unit, where the conditions were favourable and farthing per unit, where the conditions were favourable and the business was conducted with care and judgment, he might call their attention to the yield of over 8 per cent. on the entire capital invested in the Cornwall undertaking, whereas, of their other undertakings, after 10 or 12 years' working. Hawick and Grantham were the only two showing a yield of as much as 6 per cent., and in the case of Hawick the greater part of the load was power. Although none of these figures which he had given were unsatisfactory, there was, he thought, no doubt that they would have been still more satisfactory but for the war, for although they had derived some direct benefit from the war in the case of Hawick where, during the latter part of the year, the mills had been abnormally busy with large Government orders, and in the case of Grantham, where large Government orders, and in the case of Grantham, where one of the large military camps had been established and was being supplied by them, the majority of their undertakings had, on the other hand, in varying degrees distinctly suffered had, on the other hand, in varying degrees distinctly suffered from the various adverse influences resulting from the war, and he was very much afraid that some of these influences might be accentuated as the war proceeded, and even more markedly perhaps after the war, if it was unduly protracted. The Chairman dealt with the effects of the war on the towns of Dartmouth, Penzance, Berwick, Stanford, Godalming, Glossop and Camborne, where there were undertakings in which the company was interested, and also touched on the rise in the price of coal and other materials and the rise in wages for labour. Lastly, he said, not the least serious loss they had sustained had been in the inevitable disorganisation of their staff consequent upon a number of their men joining they had sustained had been in the inevitable disorganisation of their staff consequent upon a number of their men joining the Colours. Altogether they had lost rather more than 100 men, a number they could ill afford to spare from their by no means over adequately staffed stations, for theirs was a skilled business and this was no easy time to replace skilled men trained in their service. They were making good to the dependents of those who had gone any diminution in the pay they were previously receiving. Although they were bound to suffer to some extent, he saw no occasion for unnecessary depression. In suite of the war they had reached the stage when they were In spite of the war they had reached the stage when they were able to recommend the payment of the full preference dividend, and he did not anticipate that they would be unable to maintain it, but he did think that it might be somewhat longer than he had hoped before they would be in a position to resume the payment of an ordinary dividend. But, whatever resume the payment of an ordinary dividend. But, whatever effect the war might have on the immediate prospects of the business, it would not, he felt sure, affect its permanent prosperity or deprive them in due course of the fruits for which they had so long and so patiently laboured.

Sir Douglas Owen seconded the motion. In reply to questions, the Chairman said he did not think it wise to state the price at present at which they hoped to make the Cornwall company's debenture issue. The motion was carried.

#### Cleveland and Durham Electric Power, Ltd.

THE annual meeting was held at Newcastle-on-Tyne on March 29th, Mr. James Falcover (Chairman), M.P., presiding. The Chairman said the gross profits for the year amounted to £36,838, and in considering that amount it was necessary to take into account the exceptional circumstances under which the business of the year had been carried out owing to the fact that a war was going on, and that many businesses had been upset by it during the latter part of the year. It had affected that company adversely. With regard to existing been upset by it during the latter part of the year. It had affected that company adversely. With regard to existing customers, in a good many cases there was a considerable diminution in the volume of their business, and not only that, there was not a steady diminution, for they had to keep themselves in a position to supply the full demands, although to a considerable extent their demands did not reach anything like the normal. The cost of production was, therefore, increased. In the coal and ironstone area, which they largely supplied, the volume of business had been very seriously affected by the diminution of the number of men available for the work. They had also increased cost of coal, and that to a substantial extent affected their business. Anavailable for the work. They had also increased cost of coal, and that to a substantial extent affected their business. Another additional cost was due to the delay of making connections which had been already contracted for; in some cases plant which ought to have been supplied from abroad, and plant which ought to have been supplied from abroad, and other from engineering shops at home, could not be delivered because the shops had had to devote their attention to producing articles urgently needed for the war. For this and other reasons it was not possible to draw reliable comparisons between the state of their business for 1914 and the preceding corresponding periods. Under all the circumstances, he thought the gross profits were not unsatisfactory compared with what the directors, at least, thought might be their position when the war broke upon them. After providing for debenture interest, there was a net profit of £16.826, which, with the sum of £8.798 brought forward from the last account, gave them an available balance of £25.624. The directors had come to the conclusion that it was the right thing to pay a gave them an available balance of £25.624. The directors had come to the conclusion that it was the right thing to pay a dividend of 4 per cent. on the preference shares amounting to £13,348, to transfer to depreciation and renewals £3,000, as

against £2,000 for the preceding year, and to apply £1,000 towards the reduction of the expenses of the issue of dehentures, carrying forward £8,276. Referring to the work of the year, he said they had completed and connected up a very large supply to the Horden Colliery, and the plant was a complete success, demonstrating that electrical working could be

plete success, demonstrating that electrical working could be established on a large basis in all departments of colliery working. As to future business, they had at the moment contracted for further connectious to the extent of 9,000 H.P., and that included contracts with the Middlesbrough and Stockton Corporations. The company were making allowances to the men who had joined the Colours.

Mr. W. R. Armstrong seconded the report.

Mr. A. Gemmell, said he was ready to admit that the directors had had difficulties to deal with, and he believed the directors to be honourable men, but honourable men were sometimes so ill-advised as to accept a wrong policy and had not always the courage to change their course. The Board of Trade auditor had said that he could not check certain figures. Although the Cleveland group consisted of three companies it comprised one business; but there was no audit of the business as a whole and inter-company transactions on a large scale as a whole and inter-company transactions on a large scale could not be properly checked. When the control of Parlia-mentary undertakings could be acquired, as it had been by that company, without Parliamentary sanction, by buying shares in companies invested with Parliamentary powers, and when that control was exercised against the interests of consumers and of shareholders, the case was a strong one for

drastic remedy.

Mr. Chipchase asked how much the company got for supplydrastic remedy.

Mr. Chipchase asked how much the company got for supplying current, and what was their income from investments. He was very doubtful whether they ought to pay a preference dividend this year. There were too many deferred charges or liabilities against the company, including the issue of the debentures. He referred to the question of depreciation and was doubtful whether they were writing off sufficient for this purpose. It seemed to him that the financial position of the company was not yet sound. During the past year the directors had spent £48,000 on capital charges, and it seemed that they would be faced with a further capital expenditure this year, although the directors were silent on that point. To what further expenditure were they committed? Did they think the financial position justified them in making further capital expenditure? Ought not their energies to be directed to getting the best possible out of their present plant. He thought their expenses were much more than they ought to be. Unless the directors could assure them that they were strongly of opinion that the dividend could safely be paid, he moved that it be not paid at all.

The Charman said there was no point for him to reply to in Mr. Gemmell's speech. In reply to Mr. Chipchase, he said he was not quite sure that he could give all the details asked for from memory, but they had all been carefully considered by the directors. They had always refrained from giving figures with regard to their income from the supply of current, for the obvious reasons that they did not think it was the practice of companies like theirs to give figures that would show the prize at which they were supplying the current to different consumers, or even the average price. His own view

the practice of companies like theirs to give figures that would show the prize at which they were supplying the current to different consumers, or even the average price. His own view of the company was that he thought that the time had arrived when it was desirable, and he thought they were fairly entitled, to accept a somewhat higher price than in the past for current supplied. In regard to the question of dividend, he thought that when the preferred shareholders had agreed to accept a dividend which was not cumulative the fair way in which to approach the question of paying a dividend to preferred shareholders was to see what was the profit of any particular year, after making proper allowances. Every legitimate consideration had been taken into account by the direcconsideration had been taken into account by the directors, and they had come to the conclusion that the right responsibility in making it. As to further capital commitments, the directors had had in view for some time the importance of limiting so far as possible the capital commitments. There had been no avoidable expense incurred in the way of looking out for new business.

report and statement of accounts was adopted.

The CHAIRMAN moved the payment of the preference dividend and the Hon. Robert James seconded.

Chirchase proposed that no dividend be paid this year, and Mr. GEMMELL seconded, but the amendment was lost, and the motion was agreed to.

# Launceston and District Electric Supply Co., Ltd.

THE annual meeting was held on March 29th, Mr. R. B. ROGERS presiding. The report showed that the business had grown satisfactorily, and that the number of customers at the end of the year was 188, and lamps 5,020. The revenue receipts amounted to £1,130, and the working expenses to £685, leaving a gross profit of £445. The number of units distributed during the year was 50,329. The Chairman said distributed during the year was 50,329. The CHARMAN said the company were appealing against the assessment as to rates, and they believed they would get it reduced. As to the business, while it was proceeding satisfactorily, he would like to see an increase in the supply of small motors. Mr. W. H. Symons (Vice-Chairman), in seconding the motion, referred to the decrease in working expenses. The town lighting had been approved by the Corporation, and the question of extending the mains was under consideration. He paid a tribute to the Engineer (Mr. Oxenham) for his tact and careful manage-The report was adopted and a dividend of 21 per cent. agreed to.

A vote of thanks was accorded to the directors and staff, special mention being made of the services of the Secretary (Mr. F. Benoy).

# Woking Electric Supply Co., Ltd.

THE report for 1914, which was adopted at the annual meeting held on March 20th, states that the revenue was £19,292, and the expenses for generation, distribution and management were £10,415, leaving £8,876, plus £622 brought forward and £1:22 for income tax accumulations. Interest on debenture stock absorbed £2,471, interest on temporary loans £369, dividend on the 6 per cent. cum. pref. shares £2,846, leaving £2.945, out of which £1,500 is placed to depreciation and renewals fund, £500 to reserve, 5 per cent. is paid on the ordinary shares, and £653 is carried forward.

1913	 							£17,584
1914	 		 	2,021		95,803		₹,18,878

During the year the directors issued £850 4½ per cent. debenture stock, £5,379 6 per cent. cum. pref. shares, and £350 ordinary shares. Owing to the continuous growth of the business of the company the directors are still looking towards issuing further debenture stock, and ordinary shares. The expenditure on capital account on December 31st, 1914, amounted to £138,955. During 1914, over three miles of new distribution cables have been laid.

The depreciation and renewals fund account now stands at £14,395, and the reserve account at £850.

Bromley (Kent) Electric Light and Power Co., Bromley (Kent) Electric Light and Power (o., Ltd.—The directors report that during 1914 the connections have increased from 3,850 to 4,089 kW., but the effect of the war, especially during the last quarter, has been to seriously reduce the current sold. The result of the year's trading, including £1,805 brought forward, shows a profit of £13,884, and after payment of debenture interest and trustees' fees, &c., amounting to £3,013, there is a balance of £10,871. An interim dividend at the rate of 4 per cent, per annum was paid for the half-year in October, and the directors recommend the payment of a further dividend for the second half-year at the rate of 10 per cent, per annum, making a total dividend of 7 per cent. for the year, that £4.000 be placed to general reserve account, leaving a balance of £1,621 to be carried forward. forward.

Telephone Co. of Egypt, Ltd.—After providing for debenture interest, &c., the accounts for 1914 show a profit of £198,281, inclusive of £134,646 brought forward; further dividend of 6 per cent. on both the preferred and deferred shares, making the usual distribution of 10 per cent. for the year are to be paid, carrying forward £171,550.—Financial News.

# STOCKS AND SHARES.

TUESDAY EVENING.

Stock Exchange markets returned after Easter to their accustomed haunts, invigorated and refreshed by the change. Members of the National Guard who went to Brighton were amongst the few dissatisfied people, the weather having played them false for the greater part of the time. The signalling section, which was to have had tests in Morse reading, etc., was disappointed of its hopes; but, speaking generally, the old Stock Exchange joke was fairly applicable—that the principal features of the markets after the holiday were sunburnt—and cheerfulness dominated most sections.

There is still brisk demand for investment securities of all kinds, and the difficulty is to get sufficient steek to fill the

There is still brisk demand for investment securities of all kinds, and the difficulty is to get sufficient stock to fill the buyers' requirements. Gilt-edged issues are being eagerly snapped up, and the prospect of another big War Loan fails to subdue the appetite of those who are content with 4½ per cent. on their money, combined with as much security as can be expected while European war rages. Jobbers in the telegraph department retort with bitterness that they are not certificate manufacturers, when they are charged with having neither enterprise nor stock. Conspicuous amongst more speculative markets is the strength of rubber shares, where the activity is such that, anomalous as it may appear, some of the firms connected with the market put in two or three days' work in their offices during the Easter holidays.

work in their offices during the Easter holidays.

The rumour as to fusion between the County of London, the South London and the South Metropolitan companies is obtaining publicity, but it is pointed out that this probably started through the Chairman of the County of London stating

at the recent meeting that the company had acquired a block of South London shares and that a working agreement between the two concerns was not improbable. As regards the South Metropolitan Co., the report has been sufficient to maintain

the price of the ordinary shares at about 12s. 6d.

City of London shares are good at 14½, and County preference at 11½ are ½ higher. The rises in the rest of the list are well maintained, and there is little floating supply of shares—still less of debenture stocks. The coming rise in the snares—still less of depending stocks. The coming rise in the price of the current has had no effect upon quotations of electricity supply shares, so that those who expected a similar result in this department to that amongst gas securities, which fell upon the announcement of increased prices, had no cause for their apprehensions. The reason, of course, as we pointed out before, lies in the fact that whereas the gas companies are regulated by the sliding scale, those of the electricity supply undertakings are not subject to any such restriction.

Marconi shares have risen to 14, a gain of 2s. 6d., so that the company's recent circular, intimating that there would be no dividend at present on the ordinary shares, has had the anomalous effect of causing the price to harden. Expectation be no dividend at present on the ordinary shares, has had the anomalous effect of causing the price to harden. Expectation looks for the previous dividend to be maintained when the board consider it advisable to make a distribution. American Marconis have risen to 10s., on account of the prosperity which is said to have recently visited the United States, and which is reflected in very substantial rises amongst American railroad shares of all classes, from investment to rubbish. It would appear that the unfavourable effects of the war upon the States are already wearing off and that the country is

road shares of all classes, from investment to rubbish. It would appear that the unfavourable effects of the war upon the States are already wearing off, and that the country is beginning to feel the benefit of the demand from the belligerent countries for those things which the Americans are so well able to supply. Canadian Marconis are better at 5s. 6d. In the Home Railway market, Central London Assented ordinary improved to 77, and a buyer this week had to pay 78 for stock, the preferred ordinary changing hands at the same price. Districts, however, are dull at 17. Home Railways as a group are stagnant, with a tendency to depression; and this market has received none of the attention which the public are bestowing upon other investment parts of the House. The prior-charge stocks, however, are firm, the disposition in their case being much better than that governing the Ordinary issues.

New York Telephone bonds are 1½ up at 99½. Anglo-American Telegraph deferred is better, and there are noticeable rises in Cuba ordinary, "China" shares, Eastern ordinary stock, and Western Telegraphs. The last-named are ½ up at 13½, with very few shares about. The manufacturing division finds it difficult to supply the demand from investors. Henley's are a shade easier at 14½; but India Rubbers gained ½, and British Insulated are good at 11½. British Aluminium shares have fallen back to 20s. 6d., the recent report falling short of bullish anticipations, and this price is still cum. the dividend of 1s per share.

Mexican matters look a little less black: and although prices

dividend of 1s. per share.

Mexican matters look a little less black; and although prices amongst the utility companies are no better than they were a week ago, the pressure to sell is somewhat relaxed. If we were giving tips, we would venture to suggest that the speculator might find in this department useful scope for his peculiar talents. Brazil Tractions are a point higher at 53½, most things connected with the Republic having improved within the past

w days.

Armament shares are mending again, Vickers and Armongs both being slightly better. The rubber market, however, the market parties section amongst industrials. While Armament shares are mending again, Vickers and Armstrongs both being slightly better. The rubber market, however, is the most active section amongst industrials. While the price of rubber itself keeps steady, the attractions of the well-managed producing concerns have suddenly attained public recognition in a highly practical manner; so that those whose business lies along rubber paths find they have as much as they can do to cope with the work flung upon their shoulders. Probably the animation and excitement will prove transitory. Speculation being eliminated, people have to pay for what they buy; and, after all, there is not such a lot of money about that rubber shares can be bought for an indefinite period. So the market will no doubt fall upon quiet times again; but, meanwhile, orders are pouring in from all parts of period. So the market will no doubt fail upon quiet times again; but, meanwhile, orders are pouring in from all parts of the country. The wise man, of course, is he who sells when others are buying, though, in applying this axiom to rubber shares, it deserves to be remembered that, even at their advanced prices, the majority return handsome yields, and are likely to pay more in the near future.

London Electrical Workers: Threatened Strike.—
In the Times of April 1st it was stated that the electrical workers In the Times of April 1st it was stated that the electrical workers employed on repair work on shipping in the Port of London had decided at a mass meeting to strike on April 14th, unless their demands were conceded. The men are mainly employed on fitting up ships taken over by the Government. They are asking for a regular hourly wage of 1s. and a 48-hour week. The same paper states that the engineers and mechanics employed on the tube railways of London have decided to cease work on April 10th unless certain wages concessions are granted by the "T.O.T." combine by that date. Several hundred men who are engaged in the repair and maintenance work of the railways are affected. repair and maintenance work of the railways are affected.

# TEMPERATURE MEASUREMENT IN A MODERN POWER HOUSE.

BY CHAS, S. JEFFREY, A.M.I.E.E., A.Amer.I.E.E.

It should be the aim of every engineer, in order to secure maximum efficiency, to run his plant as nearly as possible under test conditions; in other words, he should make accurate measurements at short intervals of all the factors affecting its efficiency. Of these factors, the measurement of temperature receives least attention in most power houses, although having regard both to economy and to the safety of the plant it is of very great importance.

Various modern types of temperature-measuring instruments were described by Mr. Robert S. Whipple in the Proceedings of the Institution of Mechanical Engineers, No. 3, July, 1913. The types of instruments best adapted for power-house work are the mercurial glass thermometer, the indicating or recording mercurial thermometers of the Bourdon gauge pattern, and the electrical resistance thermometer.

Excluding the temperature of the furnace, the highest temperatures that have to be measured are those of the boiler flues and of the live steam, which seldom exceed 650° F.; and the lowest, that of the atmosphere.

In a complete electrical installation the following points should be fitted with thermometer elements and connected up to the temperature switchboard :-

- 1. Boiler feed-water storage tank.
- 2. Boiler feed-water inlet and outlet of economiser.
- Exit flue gases inlet and outlet of economiser.
- 4. Boiler steam header.
- 5. Main stop valve of prime mover.
- Generator stator.
- Generator inlet and outlet of ventilating duct.
- 8. Generator bearing oil pipes.
- 9. Exhaust steam to condenser.
- 10. Condenser cooling-water suction and discharge.
- 11. Hot well.
- 12. Coal bunkers.

Boiler Furnace Temperature.—In the foregoing list the temperatures of the boiler furnaces have been omitted because the temperature-measuring instruments suitable for the other sections of the plant in a power house cannot be used for this purpose. The most suitable instrument for measuring furnace temperature is the optical, or radiation, pyrometer, but such instruments can hardly be entrusted to a fireman or a meter reader.

A knowledge of the temperature of the furnace in a steam

boiler may, however, be of great value.

It is now generally recognised that the efficiency of combustion in a boiler furnace varies with the size and composition of the fuel, and that, for example, a furnace which may be well suited for burning anthracite is uneconomical when fired with bituminous coal. In burning anthracite combustion takes place almost entirely on the fire-bars, owing to the very high percentage of fixed carbon, but with bituminous coal much of the heat is obtained from the combustion of the volatile gases after they have been distilled from the coal. High temperature is necessary for the complete combustion of these gases, and for this reason it is necessary to use some form of reverberatory furnace to prevent them coming prematurely in contact with the boiler tubes and being cooled below the temperature necessary for complete combustion.

Although pyrometers for indicating furnace temperature are unnecessary under ordinary working conditions in a power house, they might well be more frequently used in boiler testing, as an assistance to the engineer in determining which is the best size and quality of fuel to use in a particular style of furnace, or, conversely, the best form of furnace for the combustion of a particular class of fuel. The degree of combustion that has been attained is given by analysis of the flue gases. The use of pyrometers in the furnace is suggested to locate the cause of imperfect combustion as shown by the flue-gas analysis.

If high-temperature pyrometers were more commonly used, improvements in the design of boiler furnaces would

[Vol. 76. No. 1,950, APRIL 9, 1915.

assuredly result. Station engineers, more particularly those domiciled abroad, are often faced with the problem of adapting their furnaces for the combustion of fuel of an entirely different quality from that for which they were

originally designed.

A simple method of estimating approximately the temperature of a boiler furnace is by the analysis of the flames by means of violet glass. The greater the intensity of the action in the boiler furnace the greater will be the actinism of the rays emanating from it; or, in other words, the more perfect the combustion the greater will be the proportion of violet rays emitted by the flames. By means of the violet glass all the rays less active than violet are cut off. In a well-designed furnace, working under good conditions, the whole of the internal surface will be incandescent, and will appear luminous when viewed through the violet glass. If the temperature of the gases is low, then dark patches will appear where the rays are less active than violet, indicating that at those parts of the furnace complete combustion of the volatile gases may not take place.

Boiler Flue Gases and Economiser Temperatures .-Measurement of the temperature of the exit gases from the boiler flues is a matter of no difficulty, and can be effected by means of electrical distance thermometers or by mercurial thermometers of the Bourdon type. Mercurial pyrometers are accurate and reliable, but, if readings are to be taken frequently, it is necessary to have one in the flue of each working boiler, because the time taken for the pointer to reach the true temperature reading is considerable. gas pyrometers of the Bourdon pattern are more expensive instruments, and are more liable to derangement, than the resistance element of the electrical thermometer. It is true that the indicating instrument of the latter is much too delicate to be installed in a dirty boiler-house in the open, but proximity to the test points is not of great importance. With electrical thermometers it may be considered necessary in a large station to have more than one switchboard,

in being able to take all the readings at one point. Usually it is not advisable to admit the feed water to the economiser at a temperature of less than 100 F. on account of the condensation of the corrosive gases from the flues which takes place against the cold tubes of the economiser. Very rapid deterioration of the economiser may take place from this cause. If no exhaust steam is available for the preliminary heating of the feed water up to about 100° F., some engineers feel justified on this account alone in using a live-steam heater. Where feed heaters and economisers are used, temperature readings are the only means available of determining the efficiency of their operation. If these readings are taken regularly, any falling-off in the performance of the economiser or feed-water heater through dirty or scaled tubes can be detected. All economisers should be fitted with thermometers at the inlet and outlet of the flue gases and at the inlet and outlet of the boiler feed

but, in the opinion of the writer, the advantage lies rather

Where means are available for determining the evaporation of each boiler, the temperature of the flue gases gives an indication of the condition of the fire-brick baffles. Low evaporation with high flue temperature will indicate that the gases are leaking past the baffles without giving up their heat to the boiler.

When the boilers are known to be in good order, the shift engineers can readily tell by means of the flue temperature readings whether the furnaces are being fired so

that each boiler bears its proper share of the load.

Neam Temperature.—When the steam is not superheated a thermometer is not necessary in the boiler header, as the temperature of the steam has a fixed value corresponding to every value of the pressure. Accurate pressure gauges are required by law, and from them the temperature can be deduced. The use of superheated steam in electrical generating stations is now almost universal, however, as the efficiency of the steam turbine increases with increase of superheat. From the standpoint of efficiency it is quite as important accurately to maintain the steam temperature as it is to maintain the steam pressure, yet in most stations a recording pressure gauge is considered a necessity, while the steam temperature readings are taken most casually. The efficiency of a boiler is the ratio of the heat units imparted to the steam to the heat units taken from the fuel. Unless a means of measuring the temperature of the steam is available the efficiency of the boiler cannot be determined.

Generator Windings.—Temperature readings of great importance, more particularly with reference to the safety of the plant, are those of the windings and cores of generators and transformers. It is impracticable to take temperature readings of the rotor of a loaded generator, but those of the stator can always be determined. It is fortunate that in turbo-alternators the rotor is seldom subjected to a pressure exceeding 100 volts, and carries a current fluctuating within comparatively narrow limits, so that the danger of an excessive rise in temperature is negligible, if the ventilating arrangements are in order. Some interesting comparisons of different methods of measuring stator temperatures were given in a paper presented under the auspices of the Standards Committee of the American Institute of Electrical Engineers, and were recorded in the Proceedings of that Institute for February, 1913. method recommended is the insertion of exploring coils in the hottest part of the machine. The authors found that the temperature rise at the hottest part might be as much as 60 per cent. greater than was indicated by mercurial thermometers placed against the core or in the ventilating If suitable provision is made in designing the generator, an exploring coil in the form of a distance thermometer element can be placed in any part of the core. Without this provision the electrical thermometer will still give higher readings than can be obtained by mercurial thermometers, because it is not subject to the restriction that it must be placed where it is easily accessible. mortality caused among mercurial chemical thermometers by poking them into ventilating slots is very high, and if they are left in the machine after it is shut down they will inevitably be broken by the cleaners.

In a modern turbine it is of great importance that an adequate supply of air for ventilating the generator should Should a thermometer not be provided in be maintained. the core of the machine itself, the temperature of the inlet Although this does not and outlet air should be taken. give the true temperature of the machine, an increase in the difference of temperature between the inlet and outlet air will indicate that the temperature of the generator has increased, or that the supply of air has been interrupted. is the temperature rise that limits the load capacity of the machine, and manufacturers' rating of load capacity may be largely discounted by the conditions under which it is For example, in some parts of India there is a operated. difference of 50° between the minimum and maximum shade temperatures. It is obvious that a machine can be run at an overload for a much longer time when the atmospheric

temperature is 40° than when it is 90°.

The writer has been struck by the diversity of opinion among the shift engineers of his acquaintance as to when a machine is sufficiently loaded; and he would suggest that after the maximum permissible temperature has been carefully determined, shift engineers should be guided by the thermometer as much as by the ammeter. The thermometer gives a steady reading, whereas the ammeter, particularly on traction generators, often varies so much as to make it a matter of some difficulty to determine what the load actually It is desirable that the thermometers should be placed in the centre of the air trunk, where the wind velocity is highest. The ventilating trunks are very often difficult of access, and to take the readings with mercurial thermometers it is often necessary that the attendant should go into them The advantage of distance thermometers in this section of the plant is obvious.

Bearings and Oil Supply.—In a steam turbine the temperature of the oil gives an indication of the temperature

^{*} The use of wet air filters reduces the temperature variation of the air available for cooling very much, because with this type of filter the air is delivered to the machine at the temperature indicated by the wet-bulb thermometer. The variation of the drybulb thermometer is always much greater than that of the wet-bulb thermometer. The wet-bulb reading seldom exceeds 80° F. in any part of the world, while the dry-bulb reading may reach 120° F., or even higher. 80° F. is a very high wet-bulb reading, and only in very humid tropical districts is that figure approached

of the bearings, provided, of course, that the rate of flow of the oil is clearly visible. However reliable distance thermometers may be, it is not suggested that they can displace or reduce appreciably the amount of attendance that is required on an important piece of plant like a steam turbine, and it would be unwise to put distance thermometers where close personal attention is required, but where very accurate determination of the temperature is not necessary. f the bearings are not readily accessible, as in a vertical steam turbine, then separate resistance elements might be placed in each of them, but ordinarily, in the opinion of the writer, it is sufficient to know the temperature of the suction and discharge pipes to the oil tanks. The oil suction temperature reading enables the supply of cooling water to the coils in the tanks to be controlled so as to maintain the desired temperature of the oil supplied to the bearings.

Condensers.—Temperature readings at the condensers are economically of great value, particularly when the cooling water is discharged to cooling towers. For every value of the vacuum, saturated steam has a corresponding temperature, and the injection water and condensate discharge should as nearly as possible approach the steam temperature. It is the function of the condenser to take only the latent heat from the steam, and if the condensate or injection water discharge temperature is below the temperature corresponding to the vacuum (or more correctly the absolute pressure), it means that unnecessary work is being done in the condenser. With jet condensers it is practicable to keep the water discharge within 3 or 4° F., and with surface condensers within 8° F., of the temperature of the exhaust steam. The advantages of maintaining high-water temperatures are :-(1) Less water is circulated through the condenser and the power consumpt of the circulating pumps is thereby reduced; (2) if the condensate is used for boiler feed water there is an obvious economy of fuel in keeping the temperature high; (3) if the water is discharged to cooling towers the latent heat of the steam taken up by the injection water is much more readily dissipated when it enters the tower at a high temperature.

Four thermometers should be fitted to each surface con-

denser, namely, in the exhaust steam pipe, the condensate discharge, the injection water suction, and the injection water discharge. In a jet condenser, of course, the condensate discharge thermometer is not required, as the condensate is carried off with the injection discharge

water.

In the opinion of the writer, the advantages of the electrical distance thermometers in this connection are very marked. The time that is required to take condenser temperatures with mercurial thermometers is too great to permit of their being taken very frequently, and as the conditions in the condenser change with every variation of load it is essential that they should be taken frequently.

Coal Bunkers.—With certain classes of bituminous coal there is considerable danger of spontaneous combustion, particularly if the coal has been stored when wet. Coal in a finely-divided state, such as slack or dross, is more liable to ignite spontaneously than large coal. It is possible for combustion to go on for a long time with very little emission of smoke, and often it is not observed until the fire has a good hold. A case is on record in an Indian colliery where the first indication that a large stack was on fire was the total disappearance of two coolies who attempted to cross over it. The weight of the men broke through the upper crust of the stack and plunged them into a burning crater, in which no trace of them was ever found. The danger of spontaneous combustion is well known to marine engineers, and the law demands that the temperature of a steamship's bunkers must be recorded in the daily log.

Various methods have been suggested for preventing spontaneous combustion; and some diversity of opinion exists as to the efficiency of the common practice of ventilating the interior of the coal stacks. Storage in an atmosphere which does not support combustion, carbon dioxide, for example, has been suggested, but there are few electricity supply stations where the danger is sufficiently great to justify the expenditure which would be necessary with such an arrangement. In most cases it will be sufficient if means are available for locating and extinguishing an out-

break as soon as it occurs.

A crude form of thermometer which is sometimes used for this purpose is simply an iron rod thrust into the centre of the stack. Any increase of temperature in the body of the coal will be readily conducted along the rod and become apparent to the touch. The method commonly used on board ship is to have an iron pipe built into the bunker and opening on to the deck, down which a maximum thermometer can be lowered and the temperature at the centre of the coal registered. This method can be used in a supply station, although the bunkers are usually more inaccessible than on board ship. A valuable application of the electrical distance thermometer is to indicate the presence of spontaneous combustion. Readings can be taken with far greater frequency than is possible with any other form of thermometer, and the elements, completely enclosed in an iron pipe, can be placed without risk of damage in the most inaccessible part of the coal heap or

In the opinion of the writer, to make it practicable to take frequent readings in a large power house, it is nece sary to install a system of electrical distance thermometers, particularly if it is situated in a country where subordinate employes who have a sense of responsibility are difficult to find. Many of the points at which observations must be made are of necessity awkwardly situated, and if the observer is required to visit each in turn it requires some strength of character to debar him from supplying many of the readings from his imagination.

A 30-point distance thermometer can be installed for approximately £150, or including depreciation and maintenance, an annual charge of about £20. For a similar installation using ordinary glass thermometers, with careless handling the annual bill for renewals may approach or even surpass this figure. The advantage of the electrical thermometer is more apparent on a large installation, however, and for fewer than 10 points might hardly justify the

expenditure under ordinary circumstances.

In a power-house electrical thermometer installation it is desirable that the switchgear should be mechanically strong, and that the switch contacts should be large. Variations in the resistance of the circuits from other causes than variations of temperature at the thermometer elements are fatal to accuracy, therefore the necessity for good connections

cannot be over-emphasised.

The writer has experienced a good deal of trouble with a well-known make of distance thermometer on account of the lightness of the switchgear. The design gives a wonderfully neat appearance, and, provided the contacts are all tight, is perfectly satisfactory in operation. with careless handling, the instrument and switches are easily deranged, and they are so delicately constructed that considerable skill is required for their readjustment.

# REVIEWS.

Boilers, Economisers and Superheaters; their Healing Power and Efficiency. By ROBERT H. SMITH. London: Crosby Lockwood & Co. Price 7s. 6d. net.

This book, like the earlier works of its author, fills us with mixed feelings, in this instance we are glad to say somewhat different from those of previous occasions.

We marvel at the author's indefatigable industry, at his mathematical genius and his determined application of mathematics to problems of engineering which, we think, have never been really suitable for such treatment.

But to begin with, is not the author wrong in supposing that steam engineering writers have not perceived, or have neglected, the fact that the radiation from the hot fuel on the grate is far more effective than any other part of the A Lancashire boiler gives, say, an evaporation of 6 lb. of water per sq. ft. of surface per hour, but it is always understood that the work over the fire grate is several times this average, and in water-tube boilers has not radiation from the fire always been credited with the bulk of the abnormal evaporation of the first bundle of tubes?

The author, indeed, admits this; his quarrel is with text-books, presumably with those rules which are based on the mean effect of heating surface. If we remember rightly, many years ago such rules did estimate fire-box surface separately from tube surface or other surface.

This book aims to correct the omission by reducing the complex laws of heat transmission to diagram form; such diagrams, if enough are asked for, will be supplied in full size, their photographed reproductions being too small for drawing office use. In reading the author's remarks we exclaim: "Is Saul also among the prophets?" for the author has endeavoured to treat of an engineering subject on what he calls simple lines, avoiding pedantic exactitude never justified by the degree of closeness with which the data of boiler practice are known. We feel that this distinct break from the author's former methods will greatly enhance the value of his present work, and as a sample let us cite what he says on the calculation of calorific capacity of coals.

The author takes the percentage of carbon in coal as actually fired on the grate, be it dry or wet, that is to say, not the percentage of carbon as obtained in the laboratory for really dry coal, but the percentage of carbon in the more or less watered coal actually fired. Then he multiplies this percentage by 17,200, and the product is the calorific capacity of that pound of coal, including its hydrogen effect and its water effect. Taking five British coals, for the rule is only given for British coals, viz, Welsh, Newcastle, Lancashire, Derbyshire and Scotch, the following figures are found:—

	Welsh.	N'C.	Lanc.	Derby.	Scotch.
Calculated heat of combustion	14,070	13,840	13,030	13,020	13,120
Per cent. of C. × 17,200	14,120	13,710	13,000	13,290	12,970
Diff.	+ 50	- 180	<b>— 30</b>	+ 270	<b>— 150</b>

The results are certainly creditably close.

But whose figures are 4,320 and 14,400 for the calorific capacity of carbon burned to its two familiar oxides? Berthelot's figures are 4,415 and 14,647, while Thomsen gives or accepts 4,350 and 14,544, which are the figures of Fabre and Silbermann. It is a pity that engineers cannot agree on the calorific capacity of both carbon and hydrogen. Why not accept Berthelot's values until there appears good reason to revise them?

Anyhow, the author's very simple formula will be welcome if we can rely upon the calculated heat of combustion as found from the constituents of the coal being really comparable with possible results.

For oil fuel the author deduces a formula  $22,200 \times \%$  C., and for samples of various oils prints the following comparisons:—

	Amer.	Russia.	Burma.	Borneo.	Texas.
Actual bomb values	19,600	19,400	18,800	18,800	19,200
% C. × 22,200	18,800	19,200	19,200	19,500	19,000
Difference	<b>-</b> 800	<b>—</b> 200	+ 400	+ 700	- 200

The weight of gaseous products per pound of fuel is 13:45 c + 1 where c is the percentage of carbon. This is the actual chemical requirement.

If the air used is n times the chemical amount the equation become 13:45 c n+1, omitting any steam from fuel wetness or from steam blowers. And so the value of n is found to be  $n=27\cdot3\times\%$  of  $\mathrm{CO}_2=0$  1, and is to be used when the percentage of  $\mathrm{CO}_2$  has been found by, say, an automatic recorder.

The author next takes up the question of the specific heat of the flue gases, or the value of h = heat given up by a fall of 1° of temperature. He finds h = 0.3 + 3.2 C n for both British and metric measures. The subject is further developed, and the author applies his formula to the same five British coals. The various other problems of a boiler are similarly treated.

We note that in his studies for this book the author has met with efficiencies greater than unity, in no fewer than our official tests; in one case as much as 15 per cent. This book is extremely interesting; the best we have seen from the author's pen, and one which gives one much to think about. But we wish the author would eliminate firstly and nextly from his vocabulary. Neither word is English, and the author in the past has employed a sufficient stock of long words without adding syllables that do not belong to these English monosyllables.

Drawing for Electrical Engineers. By G. W. WORRALL. London: G. Routledge & Sons, Ltd. Price 2s. net.

A book of this type describing the mechanical construction of electrical machines has long been sadly needed. In many electrical designs produced to-day lack of knowledge of mechanical details on the part of the designer is apparent. Methods of electrical design are now more or less standardised and uniform; it is the mechanical construction which distinguishes the products of one manufacturer from those of another. It is, therefore, surprising how little attention has been paid in text-books to the subject of mechanical design. An average second or third year student in a technical college may be fairly well acquainted with electrical design as well as with engineering theory, but ask him to design a motor end bracket with details of bearing and shaft journal—the result is generally distressing.

Electrical text-books have given the subject most superficial and often worthless treatment. Those professing to deal with mechanical construction have been treatises on engineering theory, throwing very little light on modern methods of construction.

The advent of this book setting forth features of modern construction will, therefore, probably be very welcome, both to technical students and to draughtsmen and engineers. The author admittedly does not attempt to deal with the general principles of engineering construction and drawing, but only to impart to the "young electrical engineer" an "elementary knowledge of the construction and proportions of the chief types of electrical machinery." He should at least succeed in doing this, and probably not a few "old" electrical engineers will glean some of this elementary knowledge.

The book is essentially a collection of some 70 working drawings, most of them fairly recent, by the leading manufacturers in this country, with a simple description of the principles involved in each. Bearings, shafts, A.C. and D.C. rotors and stators, and collector and brush gear, constitute the list of subjects discussed. It is rather a pity that the important subject of windings is conspicuous by its absence. One or two of the drawings shown are somewhat out of date, and the original sketches at the beginning of the book are hardly representative of modern practice. There is a contrast, too, between the detailed description of brush gear and the scanty treatment in the last chapter of slip rings. The book would probably have been of greater value had the drawings been reproduced to a much larger scale.

()n the whole, however, the drawings are good and well described, and the book is well worth its low price.

Principles of Electrical Measurements. By ARTHUR W. SMITH. London: Hill Publishing Co. Price 8s. 4d. net.

Scrictly speaking, this is a laboratory text-book, and it bears the marks of careful preparation by one who has met and appreciated the many difficulties encountered by students in the early stages of experimental electrical engineering. It is similar in many respects to the books produced for similar purposes and under like conditions on this side of the Atlantic; it is certainly no better and, perhaps, no worse than the usual type of text-book in common use in the electrical laboratories of our English Technical Colleges and Universities. But it has some important features that are well worth consideration, and even emulation, in this country.

An introductory chapter deals with units and definitions, and incidentally startles us with the following unusual definition: - "Unit resistance is that resistance in which one erg of heat is produced each second by the passage of unit Although unusual, this definition is, of course, exactly equivalent to the one commonly derived from the statement that "one erg of work is done when unit electromagnetic quantity of electricity falls through unit of potential difference." The specifications of the international ohm, ampere and volt are also included in this chapter, together with notes on the use of Weston cells, current balances and standard coils for standardisation purposes.

The author does well by beginning with the use of ammeters and voltmeters in the measurement of current, E.M.F., resistance and power. He also does well to use a paragraph to explain the application of Ohm's law to the simple circuit, and the difference between available E.M.F. and the potential difference over the whole circuit. Smith is also a humorist, for he follows up a neat and sound treatment of the subject of useful power from a cell by this problem: —"How much power is expended in an ammeter of 0.01 ohm resistance if it is connected to a storage battery of 10 volts and 0.01 ohm internal resistance? Why is it best not to try this actual experiment in the laboratory?"

The second subject treated is ballistic galvanometer and condenser methods, and all the usual experiments on E.M.F.'s and capacities are fully dealt with here and in Chapter IX. The current galvanometer is considered in the third chapter, and this naturally leads up to Wheatstone's bridge and potentiometer methods, to both of which subjects admirable chapters are devoted. The calibration and use of the simple slide-wire bridge are first described, then the "decade" bridge box (which is the American form of our Post Office box), and its use in the location of faults, and finally the Kohlrausch bridge for resistance of electrolytes and Carey-Foster's bridge for comparison of nearly equal resistances. The lack of any reference to the P.O. box is, of course, a regrettable feature from an English standpoint.

Chapter VI, on the Measurement of Current, gives some account of hot-wire, moving-coil and electrolytic methods, as well as of the Kelvin balance and electrodynamometer, while Chapter VIII deals with the application of the latter

instrument to the measurement of power.

Considerable space is devoted to magnetic measurements. and a whole chapter to the theoretical considerations of the magnetic circuit. The various standard methods for obtaining B-H curves and hysteresis loops by Hopkinson's bar and yoke, double bar and yoke and step-by-step methods are described, but a curious omission is made in that there is no reference to the magnetometric method.

There are two chapters on Self and Mutual Induction, and the multitudinous methods of measuring them, and then a final chapter, mainly of a theoretical description, on

alternating currents.

An interesting point is that the author uses the calculus quite freely throughout the book. He also misuses the word data" throughout the book, but otherwise there are very few errors either fundamental or incidental. As we have said, this book is not unique in any respect, but it can, perhaps, claim some merits, and perhaps a few defects that are not possessed by similar books already in use in this country.

# COMMISSIONS.

[COMMUNICATED.]

This does not treat of matters military; it is a brief discussion of the pros and cons of a commercial custom which has prevailed, with variations, practically ever since England boasted a commercial system.

In encyclopædic language, we are told that a commission is a pecuniary consideration, given by a principal to an agent, or to an employé, in respect of business secured by the said agent or employe, for and on behalf of the said principal. Assuming that such business proves unprofitable

to the principal and the agent or employé in no way compromises or jeopardises the negotiations, the commission cannot be withheld. This form of remuneration is founded upon an express or implied contract between the parties concerned, and such a contract may be implied from trade custom or usage.

Leaving the encyclopædic for the commercial aspect, we find that, not only in the engineering world, but in almost all fields of commercial activity, the commission problem is one of more than ordinary interest; it is, furthermore, one in which it is essential to have at the outset a clear and amicable understanding between the parties most intimately concerned, for it is easy to conceive that friction is likely to be caused by any misunderstanding arising in the absence of a definite agreement.

It is possible that this fear of petty friction is to an extent responsible for a certain chariness exhibited by some employers in regard to the wisdom of embarking upon a

commission system with their salesmen.

It is sometimes argued that if one salesman is paid a fair salary without commission, and another is working partially or wholly upon commission, the individual results of the two men, other things being equal, will be approximately This may be very plausible in theory, but it does not take into consideration that very natural facultythe human element. I do not maintain that the practice is at all common, but surely there are occasions when the non-commission man has an "easy" after a good spell of business; so, of course, will the commission man upon occasion, but there is an incentive here which tends to make such a relaxation of effort more infrequent.

Again, the commission system does not appear to be so revalent in this, our engineering industry, as in others. Why this should be so is a little difficult to imagine, but in part it may be due to the more complex and varied nature of the "lines" the engineer salesman has to sell, in contradistinction to the relatively confined scope of the commercial traveller selling tea, &c. And for this reason, that, whereas the commercial in the grocery or "soft goods" business is very frequently in the happy position of having a large proportion of his turnover provided by a more or less standardised clientele, this rarely holds, and even then to a far less proportion, in the case of the engineer. Moreover, in any given town, the former can visit many times as many grocers and drapers, as the engineering establishments that the latter can visit, while the former has also the decided advantage of being engaged in a business where it is an old-established trade custom for orders to be given to the traveller upon the occasion of his periodical visit.

Per contra, the engineer salesman is very seldom so fortunately situated; if engaged solely upon the smaller specialities of the industry, such as lamps, in which there is a certain element of "bread-and-butter" trade, he may do so, but more often the aim of the true engineer salesman is to perform some spade-work in the discussion of alternative propositions, or sometimes, it may be said, his labours are

of an educational and missionary character.

But, given the essential features of a sound working system, one which will overcome the difficulties indicated, there is no doubt that the commission system possesses advantages not to be lightly ignored. A cynic once said that "an open mind is but a polite definition of ignorance"; without going as far as this, I think it is frequently true that an open mind signifies indifference. On this subject of commissions, however, any man in a commercial position, even if connected with an establishment where commissions are not in vogue, is bound to discard, sooner or later. whatever feelings of indifference he may have had, and is forced to come off the fence, on one side or the other. necessarily means that he examines the situation with a view to seeing how the commission system affects the first person singular.

A man in employment may be paid:—

(a) A fixed salary.

(b) A fixed salary plus commission.

(c) Commission only.

Some brief comments on these, and certain of the attendant pitfalls to be avoided, may be of interest.

The first (a) needs little further comment here other than that which has already been made, but must not be

dismissed without mention of the consolation of the assured salary to a traveller who is prevented from obtaining business through external causes entirely beyond his control, and in no way reflecting upon his salesmanship and ability.

Such external causes will readily occur to everyone.

In regard to (b) and (c), commissions are almost invariably paid as a percentage in one or two forms, viz., on turnover or on profits, whilst further considerations are whether a certain initial volume of business be exempt from carrying commission, and how travelling and similar out-of-pocket expenses are to be borne. Settlement of these questions must be left to individual judgment in each case, and it should not be difficult to evolve an equitable solution.

If the commission is paid upon profits, the first question which arises is: "What are profits?" Profits may for this purpose be variously termed profits upon factory cost, with, or without, establishment charges; or they may be said to exist in the abstract, but not in the concrete, as in the case where normal profits are shown, upon the balance-sheet, but dividends are conspicuous by their absence. A more satisfactory method is to ignore profits. To some this may seem suspiciously like heresy, but the suggestion is to adjust the commission scheme upon some other basis than any which employs the elastic term "profits." This may be done by fixing a fair market price for a product, and giving the salesman discretionary powers to reduce the price within whatever limits may be arranged, but inserting a proviso that such reduced quotation bears no commission; here, again, it will be obvious that much hinges upon the "fair market price," and that, once more, is essentially a matter for amicable

Mention is made above (see Par. 2) of an employé possibly jeopardising negotiations, a possibility which indicates the necessity for a safeguard against some such condition of affairs as is suggested by the following:—Through bad engineering upon the part of one of the technical salesmen, a manufacturing establishment may find later that it is put to some considerable additional expense to complete a job in a sound and workmanlike manner, or less tangibly, for "reputation's" sake, a position which may be peculiarly exasperating, and even intolerable, if a commis-

sion to the erring salesman is also involved.

Proceeding to other aspects worthy of discussion, a common practice is to parcel out the country amongst various agents or salesmen, which is likely to cause dissension, unless the difficulties are foreseen and provided against. In the first place, it may be suggested that a salesman should reap the benefit of any and every order received from clients in his district; as it stands, this may be too one-sided, for it is readily conceivable that many orders may be received which are the result of some purely external forces, such as a trade journal reference, or a recommendation from another source. Should the salesman This is one of the most difficult problems of all, but a reasonable suggestion is that the salesman should be entitled to benefit or otherwise, according to the condition of his report book, which should contain a constantly up-to-date record of visits made, concisely tabulated and indexed.

The last problem suggests another, one very similar and possibly more difficult of solution. This is the case of a subsidiary establishment in the provinces, doing its own preliminary buying, but, for internal reasons, placing the final instructions through its head office in London. first glance, it will be remarked that the provincial salesman should benefit, and this seems to be reasonable, assuming that the London salesman is never called upon to spend any of his time on the job. But if, perchance, the London representative were obliged to render assistance, a Solomon could not always administer justice.

In conclusion, the writer would say that the foregoing remarks are in no way intended to comprise a survey of the whole of the points involved, from either aspect. Such a survey would be impossible in the space available, but if interest is aroused, he feels sure that an investigation, no matter what the result, will prove of more than ordinary interest and value, and, finally, repeats his opinion that, if only for the above-mentioned "human element," the commission system has much to commend it, notwithstanding the difficulties and problems with which it bristles.

# ELECTRIC COOKING.

MR. W. R. COOPEE'S paper on "Electric Cooking," was discussed by the BIRMINGHAM LOCAL SECTION OF THE INSTITUTION OF ELECTRICAL ENGINEERS, on March 17th. An abstract of the paper appeared in our issue of March 19th. MR. F. S. GROGAN maintained that the figures published were

those of a special case, and were not at all representative of the general results obtained. As to hot water, he admitted that for large quantities it was much cheaper to install a coke boiler, and only in a few special cases would it be advisable to put in an electric boiler. If an electric boiler was installed for convenience, electric boiler. If an electric boiler was installed for convenience, then a  $\theta$  to 10-KW, boiler should be used, with thermostatic control attached to the hot storage tank. As to the annual consumption for cooking, 3,500 should be the average result as against the author's case of 5,000 odd units. He could quote an actual case of eight in a family where they consumed 65 units per week against 110 quoted by the author. This showed that the author could not deduce general results from his special case. The outlay of £23 15s. 6d. was very high, and included 30s, for nickel plating, 70s, for switchboard, 35s, for connections, and 10s. 6d. for thermometer. Although the switchboard was included, the author paid £9 odd extra for wiring: this was a ridiculous price. The outfit £9 odd extra for wiring; this was a ridiculous price. The outfit was further inflated with £10 6s. id. for a coke boiler, which must have included £1 over list price to cover piping and erection. Why add this to the already much too high figure for the electric cooking stove when it must be granted that an infinitely better cooking stove when it must be granted that an infinitely better supply of hot water had been obtained than ever before from a coal fire? This boiler with its increased economy would pay for itself in a very few months' use. Over 30 authorities and companies were already hiring out cookers to their consumers; this had encouraged the class of consumer who appreciated the benefits of electric cooking, viz., that class where the lady herself either cooked or closely superintended the cooking. The author admitted a saving of 10 per cent. for electric cooking of meat against coal cooking, but he did not state whether the original weight included the weight of bone, which for this joint represented 20 per cent. of the whole weight. If the weight of the bone was not included, the percentage figures under the "loss" column were all too high for comparison with other public results. Also had not included, the percentage figures under the "loss" column were all too high for comparison with other public results. Also had he followed instructions instead of cooking at between 250° F. and 300° F., he would have had a less percentage loss in the electric oven. Let him consult an elementary cooking book, and he would find that after sealing the meat at a temperature of 250° F. or over for a short period, meat should be cooked at about 200° F. to get the best results. The proper place for a thermometer was in the test room, and instructions should be given to control the heat based upon the manufacturers' tests. Central-station engineers took care to see that cookers were earthed. His experience with various tariffs showed that the fixed charge plus low running costs was most useful to encourage cooking loads, but let the low was most useful to encourage cooking loads, but let the low running charge be high enough to allow a part of the revenue to be set aside to meet deficits in the charges for hiring apparatus.

The latter charge must be a low one to meet competition.

MR. T. Smith said that if the paper had not been a mischievous one he would have considered it somewhat amusing. The author had taken a very unfair, he might say artificial, case, and it looked almost as if he allowed himself to be misled into believing that the results he had obtained were representative of the results. obtained with electric cooking generally. He purchased a £25 outfit, when apparently the joints to be cooked were only about 5 lb. in weight. He must have been aware that he could purchase several outfits which would have met his requirements for less than half this amount—e.g., the Carron and the Jackson. Also utensils to the value of £2 os. were given; an absurd figure even for good aluminium utensils. The information given as to the loss of weight of meat in the process of cooking was certainly in favour of the electric cooker, although the author wished them to believe that it was not worth considering. The surprising part was, with such small joints and the heavy consumption of energy, that any saving at all was shown. The tests had been taken with ribs of beef only; if mutton, veal and pork had been included the results would have shown more in favour of electric cooking. A good cook could easily make the loss 10 per cent, on all-round cooking. The question of plugs was an important one, but the trouble would be overcome when a reliable interlocked switch and and plug was brought out. The design shown would aggravate the trouble which it was supposed to remedy. For flexible cords, no doubt the "cab tire" type was the best at present on the market. He considered that the rateable value method, with its necessary He considered that the rateable value method, which had modification in special circumstances, was the best tariff that could be offered at the present stage of our development. That it was not equitable was true; no system of charging for any commodity was. The author referred to the impossible load factor of over 100 per cent.; in practice it was possible for a consumer to have a load factor which was better than 100 per cent. from the generating station point of view. He considered the author had generating station point of view. In considered the statuter has ignored the good points of electric cooking, but had pointed out and exaggerated all its defects. Not being satisfied with the defects which became apparent to the consumer, he had gone into technical details, even outside the scope of cooking, to find defects. In his experience nothing more damning to electric cooking than this paper had been put forward, and he could confidently expect

to be put up against quotation from it for some years to come.

MR. E. P. HOLLIS said he thought that every oven should be provided with some form of temperature indicator, preferably, a cheap pyrometer. Domestic cooking and "wholesale" cooking, by which he meant cooking in restaurants, hotels and so forth, were

in totally different categories. At an hotel on the South Coast the hotel manager said that he paid for the whole of his electricity the hotel manager said that he paid for the whole of his electricity used in cooking by the extra money he received for his dripping. Bakers' ovens were affected by a number of factors which did not enter with the domestic oven. A large firm in Oxford Street, wishing to increase their output, found this impossible with the wishing to increase their output, found this impossible with the violatory oven; they were pursuaded to replace the old ovens by electric ovens, with the result that four times the output could be obtained from the same space. Previously, owing to the fact that certain forms of pastry, which were cooked after bread had been baked and removed, required particular temperatures for their cooking, the firm were not always able to decide exactly which pastry should be made until a short time previous to the taking of the bread out of the oven. With the electric oven and its easily controllable temperature all such difficulties were removed.

MR. J. H. C. BROOKING said that information received by him MR. J. H. C. BROOKING said that information received by him from central-station engineers all over the country showed that the flexible cables appeared to be the weakest point in connection with portable heating appliances. The well-known C.T.S. type was well ahead of the other types mentioned as a protection against the three chief troubles of kinking, abrasion and corrodi-

bility.

MR. G. S. CATTELL said that from the paper it would appear that the author used a cooker to cook for nine people, which was that the author used a cooker to cook for nine people, which was troubably capable of cooking for a larger number, possibly 15. On this account the consumption per person per day came out much higher than had been found to be the average amount required. It would surely be possible to provide a complete equiprent to do all the work required at a cost under half the amount ment to do all the work required at a cost under half the amount shown. Switches for the heating elements were much better if double pole, and this particularly applied to griller switches if the shown. Switches for the heating elements were much better if double pole, and this particularly applied to griller switches if the heating element was exposed. A thermometer might give some indication of the time when the oven was hot enough to commence cooking, but failed entirely if it was desired to assist the operator when requiring to change the temperature of the oven. An intelligent cook would rapidly become sufficiently well acquainted with what the oven would do, so that a thermometer in any case was not of lasting value. The question of earthing was one which could not receive too much attention, and in this direction he would endorse all of the author's remarks. So far as the which could not receive too much attention, and in this direction he would endorse all of the author's remarks. So far as the general design of cookers was concerned, manufacturers at present general design of cookers was concerned, manufacturers at present were working under a great disadvantage, inasmuch as the opinions of the engineers, who were the principal purchasers, differed widely. If domestic cookers could be reduced to fewer types as a result of agreement between engineers as to what was best, not only or agreement between engineers as to what was best, not only would they arrive at something more nearly approaching the ideal, they would also be able to manufacture under such conditions that the price to the ultimate user could materially diminish.

MR. C. O. SILVERS (communication) said that during the last 15 months he had had an opportunity of watching very closely an electric cooking and heating installation in a commercial hotel in the Midlands, which for many years had had a great reputation in the midlands. for good cooking. Electricity replaced gas in this case with the

following results:—
Up to the end of 1913 electricity for lighting was paid for at
the rate of 2½d. per unit (flat rate). The price of gas was 2s. 6d.
the rate of 2½d. per unit (flat rate). The price of gas was 2s. 6d.
per 1,000 cb. ft. With the installation of electric cooking the
tariff was readjusted as follows:—5d. per unit used, and a fixed
charge based upon £8 per KW. demand with a diversity factor for
cocasional-lights, heating and cooking. The apparatus consisted

1 double oven of the Bright	unlagged	type	3,200 v 2,400	vatte
3 800.watt hot-plates 1 double grill	•••	•••	3,000 2,000	11
s Ach fever	•••	• • • • • • • • • • • • • • • • • • • •	8,000	"
4 2,000 watt electric fires 11 light points			350	"
II III no borness			18,950	17

This apparatus replaced gas, but the following new plant was added :-

ed:— 1 hot cupboard and	carving	table	•••	•••	3,000	
2 hot water urns	•••	•••	•••	•••	1,600	99
1 electric fire	•••	•••	•••	•••	2,000	
1 + light points	•••	•••	•••	•••	450	
••					7,050	,,

The actual cost of electricity, coal and gas for the two years preceding the cooking and heating installation and for the first year of electric cocking and heating was as follows:—

Tecture cor many	 1	912.		1	913	;.	19	914.	
Coal Gas Electricity	 £35 47	10	2 2	53	0	10	£35 13 66	0	0 2 3
Total	 £110	17	6	£111			£114		

Total... £110 17 6 £111 17 1 £114 18 5

The above figures included no capital charges, but the electricity charges for 1914 included £7 2s. for the hire of apparatus. It must also be remembered that the 1914 figures included additional heating facilities, amounting to at least 2,000 units per annum. On the other hand, they had the installation of an up-to-date coal range for heating water, boiling vegetables and heating plates, &c. The 1912 and 1913 figures were obtained from meter readings taken before December 31st, so that the actual costs were greater than the figures shown. The electricity units

for 1914 were taken from January 1st to December 31st, and he might add that the amount of food cooked in 1914 was greater than in either of the preceding years. In his opinion all heating and cooking apparatus—in fact, all apparatus which was heating and cooking apparatus—in fact, all apparatus which was in any way handled—should be properly earthed, whether in the kitchen or anywhere else. He might say, as a consumer, that the results obtained during a year's working, in which 21,391 units were used at an average cost of 673d. per unit, were eminently satisfactory from a commercial standpoint. The only capital expenditure that had been necessary for these results was that to penditure that had been necessary for these results was that to cover the wiring of a few flat-bottomed pots and pans.

# DISCUSSION AT MANCHESTER.

MR. WELBOURN said that as the result of about three years' experience of electric cooking he agreed with many of the author's MR. WELBOURN said that as the result of about three years' experience of electric cooking he agreed with many of the author's recommendations. Regarding energy consumption, 1½ to 2 km. I hours per person per day according to season was the average. It was very desirable to mount control switches on the wall, and if the supply was from a three-phase A.C. system a double-pole switch should always be used to isolate the apparatus entirely. Not only cooking apparatus, but every power circuit such as for radiators, cooking apparatus, but every power circuit such as for radiators, about describe so arranged that the appliance itself could be earthed. He had used flexibles of various types domestically for about eight years, and had discarded rubber-insulated flexibles entirely and adopted flexibles insulated with asbestos and bound with thread; these were entirely satisfactory after 18 months' use, and withstood heat and ill-usage much better than rubber flexibles. Accurate accounts of the heat bill for a family of eight were kept for two years, which showed a total difference of 25s, between the electric cooking year and the coal year. Electrical energy was supplied at 1d. per unit flat rate with 2½ per cent. discount, and coal coat 17s, 6d. per ton average. The apparatus installed by the author appeared much larger than actually required by the household and would probably accommodate 50 per cent. more persons. The speaker's apparatus had a maximum demand of 4 km., whereas the author's maximum demand was apparently about 7½ kw. The cost per meal served was heavy when the apparatus the author's maximum demand was apparently about 7½ KW. cost per meal served was heavy when the apparatus was larger than was required. In his opinion the time was near when domestic consumers would be charged on the contract basis involving maximum demand.

MR. W. CRAMP could not understand why electric ovens should not be mounted at a reasonable height. The plan of putting a thermometer on the oven door seemed useless; the proper place was inside. The author seemed very optimistic regarding the question of earthing, when he stated that possibly in those towns question of earthing, when he stated that possibly in those towns where the supply undertaking had a wiring department this part of the work received proper attention. The speaker's experience showed that it did receive proper attention by the wiring department if it was contractors wiring, but if the wiring department if it was contractors wiring, but if the wiring department out the work, anything would do. A case was recently discovered where a circuit carrying 500 amperes was earthed by Corporation workmen. A No. 18 wire was twisted round a loose nut on one of the switches, and then soldered to the end of a lead water pipe which was hanging loose from a roof. Three contractors were engaged on this installation besides the Corporation, and whilst the former put in enclosed fuses, the latter installed bare wire. MB. W. CRAMP could not understand why electric ovens should be mounted at a reasonable height. The plan of putting a

MB. ALDERMAN WALKER thought the electric cooking load was MR. ALDERMAN WALKER thought the electric cooking load was one to be sought after. About a year ago Manchester adopted a new tariff in order to attract the cooking load, viz, 12½ per cent. on the rateable value, plus ½d. per unit metered. It was also stipulated that houses under £30 rental should install 2 kW.; £30 to £50 houses houses under £30 rental should install 2 kW.; £30 to £50 houses nouses under £30 rental should install 2 kw.; £30 to £50 houses 3 kw.; and over £50 4 kw. 'The response to the tariff was very poor, and after considerable investigation the cause was found to be the inadequate wiring of the houses originally. A prospective user of cooking plant would not entertain the idea of rewiring his house, involving the destruction of plaster and fittings. A note had been prepared by the department for circulation amount had been prepared by the department for circulation amongst had been prepared by the department for circulation amongst architects, builders and house owners requesting steps to be taken architects. to ensure sufficient copper being put into new premises to admit of radiator and cooking loads. The capital cost given by the author or the family mentioned seemed excessive.

PROF. E. W. MARCHANT said the best cooks were the most stupid

PROF. E. W. MARCHANT said the best cooks were the most stupid and he did not believe thermometers to be of any service to such persons. Regarding small electrical appliances, the weak spot was certainly the flexible. The time taken for repairs was usually much too long, and easily replaceable elements were to be advocated. The secondary charge should be kept down in order to induce consumers to use energy. It seemed grossly unfair that the primary charge should have any bearing upon the amount of garden attached to a house: a charge based upon the cubical contents or thor space of the house would surely be more reasonable. The cooking consumer was evidently a very desirable one for the electrical engineer.

electrical engineer.

MR. HOLLINGSWORTH said that at St. Helens with a rateable value system and a secondary rate of \$\frac{1}{4}d\$, per unit they had been value system and a secondary rate of \$\frac{1}{4}d\$, per unit they had been fairly successful. The initial outlay on apparatus and wiring was the chief drawback, together with the competition of gas cookers with gas at 2s. per 1,000 cb. ft. There would be no difficulty in meeting the gas competition successfully were it not for the cost. meeting the gas competition successfully were it not for the meeting and unreliability of large cookers. A large wo of installing and unreliability of large cookers. A large works employed electricity for cooking for 18 months with every success excepting in the matter of reliability. In the hands of experienced cooks the results were far more satisfactory with thermometers than without. The author did not say too much about the necessity of earthing cooking apparatus. The three-pin plug was a sity of earthing cooking apparatus. The three-pin plug was a very satisfactory device, and it was hardly possible for a negligent wireman improperly to earth apparatus fitted with such plugs, A large works

Gas

He advised engineers who had not yet adopted a rateable value or double-charge system to do so, as the half-watt lamp would doubtless arrive and place them in a worse position than when the

metallic-filament lamp was introduced.

ME. W. Eccles gave details of equipment and costs in the case of his own house, assessed at £30, and usually accommodating three adults. The equipment was as follows:—

three adults. The equipment was as lonows.—

Electrical—Lighting on a generous scale throughout.

Cooking by means of a cooker comprising oven, grill, hot closet and four boiling plates, also a number of self-contained utensils.

Heating by means of portable radiators.

Power for washing, vacuum cleaning, fans, &c. For washing boiler and hot water for house supply

when kitchen fire was unavailable.

Coal— During winter only for kitchen and one room fire.

Electricity cost ½d. per unit plus 12½ per cent. of rateable value. , 2s. per 1,000 cb. ft.
, 1s. 0½d. per cwt. approximately. Gas Coal

The accounts were :

Quarte	r endi:	ng	Sep	t., 1	914.	Dac	., 19	14.	Marc	h,	1915.
Electri	city	• •••	€2	16	7	£2	12	1	£3	4	51

			£3	15	0	£4	0	01	£ŏ	9	01

which represented about £17 12s per annum. There had been a saving in laundry, carpet cleaning, baking and charwomen of about £13 per annum. The alvantages derived were—

1. Less of the drudgery of housework and increased cleanliness,

2. Comparative independence of maids.

2. Comparative independence of maids.

3. Comforts and luxuries otherwise unattainable at any price. The author's case, whilst being devoid of the aforesaid advantages, except perhaps a little extra cleanliness in cooking, showed a loss of £8 18s. 9d. This loss was reduced to £1 12s. 6d. if the cost of electricity was adjusted to the speaker's rate. Further, coal at £13 10s. per annum for eight or nine persons was very economical, and probably much below the average. On the whole, the author's apparent results were likely to be discouraging to prospective consumers, as the average layman would not trouble about explanations. It appeared that the maker of electrical overs followed gas-oven practice by constructing tall, narrow ovens, which was quite undesirable. The fact that the lower 6 in. or 8 in. of a gas oven was only utilised for distributing the heat from the burners seemed to only utilised for distributing the next from the burners seemed to be quite overlooked. An electrical oven should never be less than 16 in. × 16 in. plan area, with a height varying from 12 in. upwards, according to the capacity required. The electric grill was practically perfect, but efficient reliable plate warmers and boiling plates were still lacking.

Mr. H. RATOLIFF thought electric water heating was an expensive layers at 14 per upit and only became worthy of one

expensive luxury at \(\frac{1}{2}\)d. per unit, and only became worthy of consideration on the score of convenience and cleanliness; \(\frac{1}{2}\)d. per unit was a reasonable financial proposition. The most efficient heaters were, undoubtedly, those of the geyser type, in which water flowed through the heater as required, but there were serious objections, one of which was the enormous KW. demand for a few minutes which would not permit of a reasonable tariff. A further minutes which would not permit or a reasonable tarin. A further disadvantage was the necessity of reducing seriously the rate of flow in order to obtain high temperatures. Tests carried out on a flow in order to obtain high temperatures. Tests carried out on a model heater of this type showed a water inlet temperature of 60° F., outlet temperature 110° F., flow 7‡ gallons per minute, efficiency 98'1 per cent. The load on the meter was 7 kw. The efficiency fell as the temperature was increased, and eventually when a temperature of 200° F. was reached the flow became very matchly and close characters. unstable and slow, about † gallon per minute, and the efficiency dropped to 94 per cent. The solution of the problem was, undropped to 94 per cent. The solution of the problem was, undoubtedly the thermal-storage system. Regarding electric cookers, there was not much likelihood of progress so long as the consumer

Ms. Alcook considered it a very difficult matter to interest the ordinary householder in electric cooking so long as the hot water problem was unsolved. Houses at £30 to £50 a year rental water problem was disorved. Houses at 250 to 250 a year rental had a fire in the kitchen for hot-water supply, and the cooking was done on the fire as a by-product. Regarding the design of cookers, hot-plates, &c., the efficiency of the apparatus was largely dependent upon the intimacy of contact between the vessel and heat elements, and in many types of apparatus the surface of the vessel was ground in an attempt to obtain the desired intimate contact. The gas cooker flame impinged on the vessel to be heated, and this was a good lead for the electrical engineer to aim at in getting the heat element in direct contact with the vessel to be heated. Some such arrangement was being exploited, using heating elements laid in troughs of heat-resisting material, the elements almost touching the vessel.

MR. A. G. COOPER said that cooking vessels, especially those made of aluminium, were liable to warp after a time. Regarding rateable value, he found the most equitable charge to be 12½ per cent. on £15, 15 per cent. on from £15 to £30, and 20 per cent. for anything over £30 rental.

cent. for anything over £30 rental.

ME W. R. COOPER, in reply, said with regard to the size of the apparatus, that one must consider not merely the size of one's family in normal times, but the possibility of having people in to dinner and so on. He thought the high price of cooking apparatus was largely a question of establishment charges and experimental costs, which no doubt would come down enormously if the quantity could be increased. The idea of giving notice to builders was an excellent one and ought to do a great deal of good, because the wiring was undoubtedly the difficulty. His cook was very stupid, but he had had no difficulty in getting

her to take on the thermometer. Though she does not speak much about degrees, I believes she does not mind talking about 250 in the least. He had been taxed on several occasions with having a high charge for wiring. He thought it was high himself, but the supply undertaking said it was quite normal. The supply undertakings should take this in hand very carefully and decide how cheaply and satisfactorily wiring could be done; it was a very important point.

Mr. George Wilkinson, electrical engineer to the Borough of Harrogate, has found it necessary to address the following letter to the Editor of the Journal of Gas Lighting:—

"Dear Sir,—In perusing your 'Electricity Supply Memoranda' in your issue of the 30th, I find that the writer grossly misrepresents my statement as to water heating made during the discussion on Mr. Cooper's paper at the Institution of Electrical Engineers. Moreover, your writer casts aspersions upon the cleanliness of myself and members of my family which appear to me to be in very bad taste.

What I actually said was that the electric heater has a oubical capacity equal to 12 gallons, but it is equal to an output of over 60 gallons of water per day at 100° F., which, I think, you will agree is a fair supply for a small household; it is found sufficient for two or three baths per day in addition to the ordinary kitchen

requirements.

I have facilities for the production of ten times this amount of hot water if necessary, but the output of the electric heater is

found ample for ordinary every-day demands.

"I hope you will do me the justice to have this matter put right in your next issue.

"(Signed)

"Yours faithfully/ GEO. WILKINSON."

# NEW ELECTRICAL DEVICES, FITTINGS AND PLANT.

# Giassware to Give Sunlight Colour Value.

In response to a number of inquiries for glassware which will ensure artificial light of daylight value, the BRITISH THOMSON-HOUSTON CO., LTD., of Mazda House, 77, Upper Thames Street, E.C., are putting on the market a complete range of colour matching pendants and globes. The name "Trutint" has been given ing pendants and globes. The name "Trutint" has been given to this glassware, and it is available in various compositions to ensure different sunlight values.

In Group I, the composition of the glass is such as to ensure accurate matching in colour comparison work; this particular unit is not intended for general room lighting, and is only available as a pendant reflector unit, without cabinet, for use where there is little extraneous light to interfere with colour matching. Group II is for general illumination, and gives a light of "noon" sunlight value; it is particularly suitable for lighting in paint shops, lithographic plants, art galleries, &c. The watts per candle efficiency of Mazda half-watt lamps when fitted with this particular type of globe is practically equivalent to that of standard Mazda lamps in a white onal globe

Mazda lamps in a white opal globe.

Group III is also for general illumination, and gives a light of "afternoon" sunlight value. The purpose of the Trutint globes in this case is to furnish a light that is slightly more efficient in in this case is to furnish a light that is slightly more efficient in watts per candle than Group II, and necessarily somewhat yellower, as is the case with afternoon sunlight. The Trutint globes in this group, therefore, compromise between colour and efficiency, and their field will be found in the general lighting of dry goods and clothing shops, or in other positions where daylight quality of light is desired. They are made of Trutint glass cased over by a light opal, or a very light opal body in which Trutint has been mixed, and are known respectively as "Trutint Cased" and "Trutint Opal." The cased glass appears white when unlighted, while the other units appear bluish. When possible complete installations of Trutint glass should be obtained, so that the yellow light of other lamps may not be present. other lamps may not be present.

Trutint glassware is not made for use with ordinary Mazda lamps; it has been specially compounded for Mazda half-watt lamps, which, owing to their high intrinsic brilliancy, are more like sünlight in colour than previous incandescent lampe.

# A Parsons Paraffin Motor.

THE PARSONS MOTOR Co., LTD., of Southampton, have recently built a number of 90-H.P. six-cylinder paraffin engines, both for commercial and Government orders.

The type of engine is a regular pattern 90-H.P. six-eylinder set, having cylinders 6½-in, bore and 8-in, stroke, and running at 550 R.P.M.

The leading features of the design are that the pistons and connecting rods are removable through crank chamber doors, without detaching the cylinders or separating the crank chamber. There is a complete system of pump lubrication, combining an oil cooler on the engine, and including the usual relief valve, pressure valve on the engine, and including the usual relief valve, pressure valve, and level gauge, and in order to keep down heat from the external surfaces of the vaporisers they are water cooled, and are arranged for starting by blow lamp or petrol. The engine has its own pumps for circulating the water through the cylinder jackets, &c., and these jackets are carried right down to the base, keeping the engine very cool; a centrifugal high-speed governor is mounted at one end, and controls the speed within close limits. 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to 10 to

These engines are supplied with or without compressed-air starting, and it will be seen that there is a chain turning-over gear at one end; in the example shown there is a separate air compressor driven by a friction clutch, which can be disengaged by a

At the fly-wheel end of the engine there is a distributing valve which admits pressure air to all six cylinders in turn, thus ensuring a quick start, the cylinders, of course, being fitted with non-

To give good regulation also, the drop from the cells to the end light must be small, which again means increasing the cable to the house.

By putting the batteries up at the house, the size of the mains from the engine room can be kept down merely to the size necessary to carry the charging current of the battery, and, if necessary, and to a considerable down in release to the battery and in the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same and the same

quite a considerable drop in voltage may be allowed in them.

A battery regulating switch, suitably enclosed, with merely a regulating handle projecting, can be fixed in the wall of the

battery room looking into a passage, and any one of the indoor servants can be told off to move the handle one way or the other, so as to keep the pointer of the voltmeter fixed over it at

a definite point.

I generally fix the size of the engine to give the specified charging current at about 2'2 volts per cell, which means that at the end of the charge, when the voltage has risen to, say, 2.6—2.7 volts, the current falls off, thus giving an economical rate of charge. thus giving an

In only a very few cases in this country is there water power of practical use available; and in most cases some form of heat engine is employed. In certain special cases where

steam is required for heating, and the exhaust steam, after passing through the engine, can be utilised, the steam engine is the most economical source of power, but such cases generally arise only in works or business premises where little or no light is used in summer, but only in the winter, when steam is wanted for heating as well.

meating as well.

Where town gas is available, a gas engine, with belt-driven dynamo, makes a good combination, especially as the engine can be always run at its most economical load when charging the battery. Taking an average figure of 85 cb. ft. per unit generated by the dynamo, with gas at, say, 3s. 6d. per 1,000 cb. ft., the cost of fuel per unit generated is 1'46d.

Not more than 60 per cent, of the total energy generated by the dynamo can be obtained from the battery, and thus the cost per unit actually used in the lamps will be 2'43d. for fuel

Where town gas is not available, a suction gas producer is frequently used, consuming anthracite, or, in some cases, coke. The quently used, consuming antiracite, or, in some cases, coxe. In a cutual consumption per unit generated during last year of such a plant put in to our specification at a large country house was 2.2 lb. of anthracite at 26s. = 0.31d. Such plants are simple and easy to work, but like the steam boiler, are not so economical when worked only intermittently as when they are in regular use all day long. This difficulty is overcome by the different forms of oil engines, none of which consume any fuel except when they

ne engines which are most generally used are horizontal single-cylinder oil engines burning paraffin. They are very simple, quite reliable, easily started to work, and can be safely left in the hands of any intelligent gardener. The consumption of paraffin is about 1 pint per unit generated, which, at 7d. per gallon, costs 0.875d. per unit.

The petrol engine, direct-coupled to its dynamo, has been largely used for country house lighting. It makes a very nest, compact set, and is easily understood by the chauffeur, who is mostly to be found on large estates. The consumption of petrol per unit found on large estates. The consumption of petrol per unit generated is about 1½ pints, which, at 1s. 9d. a gallon, costs nearly 4d., so that as regards fuel costs these sets do not compare favourably with paraffin engines. There is more risk of fire, due to the use of the inflammable petrol instead of the heavier paraffin oil, and the electric ignition certainly gives more trouble than the hot-bulb ignition. Whereas one of the horizontal paraffin engines can, and will, run for years with nothing more than ordinary cleaning and attention by a more or less unakilled attendant, the petrol engine must have constant supervision. vision.

The Diesel engine burns the cheapest of oil fuel-

residue oil of about the consistency of treacle.

The consumption of orude oil is only about 0.7 lb. per unit generated. At an average price of 60s, per ton, the fuel cost per unit generated works out at 0°225d., but the first cost of the Diesel engine is very high, and very skilled attendance is necessary, so that except in special cases, where the plant is worked very long hours and the cost of fuel is therefore very important, it is not suitable for private lighting plants.

Questions on various points were dealt with by the author. With many reservations, he thought the average life of a battery was probably seven years, but he could point to cases where bat-teries were in existence after 15 years of working, and they were at the present moment up to full guaranteed capacity; that was because a maintenance contract had been entered into with the makers, and the plates renewed by them from time to time as necessary. The extra cost of petrol over paraffin in very small sizs was negligible, and direct-coupled petrol sets were very satisfactory for small power generators if not run at too high speed. In practice it was generally found that automatic plant required

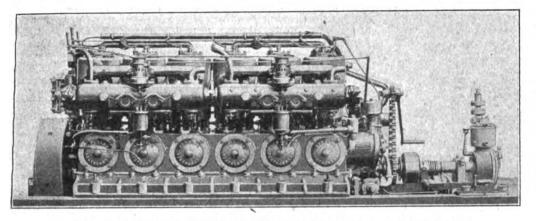

FIG. 1.—PARSONS 90-H.P. PARAFFIN ENGINE WITH COMPRESSED-AIR STARTING.

A good point about these engines is that any fumes venting the crank chamber are not allowed to pass into the engine

from the crank chamber are not allowed to pass into the engine room, but are drawn through and consumed.

Several of these engines have recently been put down for the generating stations at various military camps throughout the country, and a number are in use also by the Admiralty in different types of craft.

The weight of the engine shown approaches a couple of tons.

#### PRIVATE GENERATING PLANT.

OF taking the chair as the first President of the ASSOCIATION OF SUPERVISING ELECTRICIANS, Mr. A. H. DYKES delivered an address on "Private Generating Plants," of which the following is an abstract :

The voltage of supply, and therefore the number of cells, depends the length of main to the light farthest from the battery

on the length of main to the light farthest from the battery room. In a case where an installation on completion did not give satisfaction, I found that the battery was a 50-volt one, and that owing to the house being a long, straggling one, at the far end there was a blink in the lights every time other lights were turned on or off. The remedy was obvious, especially as the battery was small for the work—it was to double the number of cells and raise the voltage to 100.

In several cases where the lights were spread over a large area, and the dynamos were situated a considerable distance from the cell room, I have wired the premises on the three-wise system, with two batteries of 100 volts each, the two batteries being charged in series at 200/160 volts, with a change-over switch, so that the cells are changed over each day from one side of the system to the other, in order to ensure that each half of the battery gets approximately the same amount of use. This plan emables one to use small candle-power 100 volt lamps, whilst obtaining the economy in the mains and sub-mains due to 200 volt distribution.

Experience tells me that the owner of a house never com-

Experience tells me that the owner of a house never com-plains that his cells are too large, but does very frequently blame somebody because his cells were not put in large enough blame somebody because his cells were now put in the first place. A safe rule to follow is to decide the maximum number of ampere-hours likely to be taken from the longest winter's day, and then make the battery on the longest winter's day, and then make the capacity of the battery double this, thus enabling the supply to be given from, say, Saturday morning till Monday morning, without having to run the engine. In summer time it will only be necessary to charge once or twice a week.

By capacity I mean not the capacity of a new battery, but the

capacity the makers will guarantee under a maintenance policy, which with some makers is only 80 per cent. of the listed rating of the cell.

Since the introduction of the metal-filament lamp the capacity of the cells required for lighting has been very greatly reduced, but, on the other hand, the use of small motors and heating appliances is becoming much more general, and a few radiators d for some hours every night need a considerably augmented battery power.

Wherever possible I prefer to have the cell room as near as consible to the house, putting the engine and dynamo in a separate house far enough away to avoid annoyance from smell or noise.

If the battery and engine room are together, it generally means that they are some distance from the house, and as the maximum current of the battery is generally in excess of the dynamo current, the mains from the engine room to the house have to be larger, and consequently more costly, than they need be.

THE ELECTRICAL REVIEW. [Vol. 76. No. 1,950, APRIL 9, 1915.

frequent skilled attention frequent skilled attention. A maintenance contract with the makers of a battery relieved the owner of a great deal of responsibility; and the amount paid for upkeep was really depreciation as well, as the makers would guarantee to keep the battery up to its full capacity.

# BRITISH ELECTRICAL PATENTS APPLIED FOR OR COMMUNICATED BY RESIDENTS IN GERMANY, AUSTRIA OR HUNGARY.

The following list of British patents, applied for or communicated by residents in Germany. Austria and Hungary will be found of interest to manufacturers or others desiring to avail themselves of the provisions for Compulsory Licence under the new Patents Act. Intending licensees should, however, not assume without further enquiry that any patent in the list is not already assigned or licensed or that the applicant is an "enemy subject."

The list is specially compiled for the ELECTRICAL REVIEW by Messrs. W. P. Thompson & Co., 285, High Holborn, W.C., and 6, Lord Street, Liverpool.

# THE UNIVERSAL ELECTRICAL DIRECTORY

#### 1915 **EDITION**

MOW READY.

H. Alabaster, Gatehouse & Co., 4, Ludgate Hill, London, E.C.

#### THE **STATUS** OF THE ENGINEER.

AT the "mid-year convention" of the American Institute of Electrical Engineers, which was held in New York on February 17th, a number of papers were read on the subject above-named—a subject of perenuial interest, which is well worthy of the attention which is periodically drawn to it both in America and in this country.

The paper read by Dr. E. W. Rice, jun., president of the American General Electric Co., is reproduced in the current issue of the General Electric Review, together with an excellent editorial on the matter under discussion.

The author of the latter draws a striking contrast between the ship-of-the-line of 1815 and the "superdreadnought" of to-day, pointing out that in the former there was hardly a single mechanical appliance, except the pumps and the capstan, whereas the modern battleship is equipped with engines of 60,000 HP. and upwards, and is a gigantic aggregate of engineering devices - "a most highly developed organism with man-made organs." He might have added that the very latest type, the U.S.S. California, is to be propelled and operated by electrical power; but for the purpose of his argument the definition of engineering is framed in the broadest sense, embracing not only the various branches of engineering as commonly understood, but also all scientific work in which educated men are engaged. At once this fundamental fact stands out -that whereas the admiral of old was himself well versed in every technicality of seamanship, the modern commander is absolutely dependent upon his engineers in the handling of his ship, the feeding, training, and firing of his guns, the discharge of his torpedoer, and every other major operation that takes place upon the ship in peace or war. the admiral now, as then, is in supreme command, and it is only in recent years that the engineer has been accorded the rank of an officer - indeed, in the British Navy he has only been given full executive rank since the outbreak of the great war in which he is playing so essential a part.

The same general condition, the author continues, exists in all our industries; inception, development and successful operation are due to the engineer, who is the one indispensable factor without which progress would cease. "Yet he neither controls them nor dictates the policies of the thing of his own creation, and what is of more importance, he apparently is constantly seeing others reap the harvest for which he has so diligently sown." What is the cause of this phenomenon?

By way of explanation, the author suggests that when the engineer is really successful in the material sense, besides doing engineering work he becomes active in organising the work of others, and thus in time becomes a successful manager or business man, with greater financial rewards, and is lost sight of as the engineer. Again, in many fields his work has been so well done that other

less skilful can carry on the routine that he has laid down, and "the engineer has displaced himself by the product of his own brains. Indeed, in the field of operating engineers this is particularly noticeable, where the perfection of mechanical and electrical devices has been brought to such a state that the engineer holds much the same position as a lifebelt—for the greater part of the time he is not wanted, but when he is wanted his services are imperative if a disaster is to be avoided." Thus many men of good engineering training have to perform work which those with a less costly preparation could perform almost as well, and the result is necessarily dissatisfaction, not because the work is not congenial, but because the material reward falls so far short of that which corresponds to the expensive education and self-sacrificing labour of their younger days.

The author sees in this a danger for the future; if the feeling prevails that it is not worth a young man's while to enter the engineering profession, we are not going to progress in the future as in the past. "The engineering profession is giving more to the world than any other profession, and it is essential that it should be attractive to the young man of the future."

On the other hand, it is pointed out that there is another side to the question: in one sense the rewards in the engineering profession are far above those in most other pro-The engineer has the immeasurable joy of "It is the intense interest in striving for achievement. accomplishment that makes the engineering professions what they are, and has made the engineer the man of courage and resourcefulness, of patience and determination, of self-sacrifice and unending work." "The engineer must often have the idea that he is being exploited by others because of this very loyal devotion to work rather than to self-interest, and undoubtedly this has been the case in many instances," but the author sees hope for the future in the very fact that the engineer has changed the world to such an extent that nowadays commercial men have to know more of the engineer and his work, and this should lead to a more perfect understanding and a better material reward for the engineer. "Any factor in our great scheme of life that is so absolutely indispensable to our future progress must surely hold an enviable position in years to come."

Undoubtedly there is much truth in this analysis of the position of the engineer in the world's activities. That his merits are now beginning to be recognised by the public, we think, is as certain as it is that he is developing a divine discontent with his present position, and a healthy disposition to claim more adequate recognition of his rights. Both these tendencies are salutary and worthy of encouragement. The upper value of a man in the world's eye is usually limited by the value that he places upon himself; on the other hand, he must live up to or beyond his standard of value, if he wishes to maintain it. In the past, the engineer, as a class, has done the latter whilst meekly accepting the valuation placed upon him by the layman, who, being a business man, has not hesitated to take full advantage of his opportunities. It is for the engineer to remedy this state of things, and to assert his claim to an honoured position in the ranks of modern civilisation.

# THE MARKETING OF BRITISH GOODS ABROAD.

THE question of how to market British goods abroad formed the subject of an address which was delivered at the Holborn Restaurant on April 9th by Mr. C. Hamilton Wickes, H M. Trade Commissioner in Canada, who is Home on another of his welcome and profitable visits to this country, at a meeting of the Sales Managers' Association.

Mr. Wickes stated that British trade to-day was largely permeated with the leisurely ideas which prevailed in the eighteenth or nineteenth century, and these conditions were affecting the trade and commerce of this country at present. Changes had taken place in the meantime, but we had only recently recognised the necessity for reorganisation, without having, however, a clear conception of what we wished to reorganise and what we desired to effect by reorgan-It was impossible for us to see ourselves as others saw us, because we spent the greater part of our commercial life in these small islands, whereas, in order to obtain a true conception of our shortcomings, we ought to pass more time in overseas markets, studying how our goods were selected in competition with foreign merchandise of It was essential to approach the the same character. problem with open minds, and prepare to discard our preconceived notions, and to start anew. As to the criticism passed on British manufacturers that they did not make articles to the particular design, stamp, or pattern required in a particular market, he mentioned that the last thing the Americans would do was to alter their patterns to suit anybody. But in the case of many articles made in the United States, it was found that they were also adapted to the requirements of other countries. The speaker had experienced great difficulty in getting information from those who complained of British firms not producing according to particular patterns; but where he had been successful in doing so, it turned out that the order had been offered either to a manufacturer who was months behind with his deliveries, or to one who was already working at full output. If the people who complained were a ked why they did not approach other firms, they gave various reasons, including the assertion that other firms did not know the conditions in the Canadian market, and that they did not wish to approach an export agent. The reports of some of the United States Trade Commissioners attributed a great deal of the success of British trade to the credit which was extended to customers, but that applied to the merchants and not to the manufacturers.

Proceeding to consider the problem of the transportation service, the Commissioner asked whether it was not a fact that prior to the war Continental shipping companies could enter British ports and obtain as much cargo as they could carry, provided the rate was 6d. per ton less than the British rates. If a British company went to a Continental port could it get cargo on the same terms and conditions and have the same facilities for securing wharfage space? Perhaps that was one of the reasons why our shipping companies made arrangements with their Continental competitors to keep to the carriage of their goods so long as they did not come into British ports to transport British goods to foreign ports. The system of production in Great Britain was labouring

under many artificial restrictions. For instance, Australian buyers obtained a quotation f.o.b. from a British firm from a British port and a quotation from a Continental firm from a Continental port, but they wanted to know the cost laid down in Australia. Could they go to a British steamship company and ascertain the freight rate to Australia? They could go to any German firm and get a quotation for any commodity at once. Why did not the railway companies and the ocean steamship companies publish their Why were German freight rates used in this country from German ports to oversea ports? The quotation for freight from Antwerp to Melbourne on a certain commodity by a German shipping line would be more or less approximately the same as from an English port to Australia. After referring to the control by foreigners of raw materials in our Colonies, as, for example, thorium, lead ores in Australia by Germans, and nickel deposits in Canada by Americans, Mr. Wickes suggested that it would be of advantage if a reform were made by the disclosure of the real names of the importers and exporters of goods where trade was entered in the names of agents, this being a measure of protection, as also was our system of weights and measures, against foreign competition in the home market, It would also be of advantage if tariff or no tariff. foreigners who commenced business here were registered as well as those who acted as agents or branches of foreign manufacturers.

If they proceeded from business done through retailers and dealt with articles which required demonstration, they entered upon a class of commodity which needed expert selling. If they took the view that there were no manufacturers who could compete with the British in quality, the necessity for expert salesmanship became more apparent. Approximately 70 per cent. of the goods exported from the United Kingdom passed through the hands of merchants; from 1 to 2 per cent. was distributed in foreign markets from the offices of British firms in this country, whilst the devolved upon oversea representatives. merchants did not cover all the markets in the world; where they had no connection our foreign competitors the Americans and the Germans -had had it all their own way. Where the merchant connection was small our trade dwindled or barely held its own, whilst that of foreign rivals rose to an astonishing extent. The conclusions arrived at were—(1) British goods reached a certain volume and value in a certain limited number of markets overseas by the help of the merchants; (2) the other markets were very slightly worked where there was not a connection, and few British goods reached them; (3) the larger volume of trade done in the markets with which merchants traded, obscured our weakness in relation to other markets; and (4) the merchant system had operated to enfeeble and atrophy the British manufacturer's power to sell.

The speaker proceeded to remark that unless British manufacturers sent out representatives to other countries they could not acquire the necessary knowledge of invoicing, freighting, packing, exchange, &c. They were in about the same position as foreign manufacturers held in the eighties of the past century when they started to undertake an export business. The question was, how they could get the information which their rivals secured and upon which they had since built up their businesses. If no attempt was made to travel, how could they get salesmen travellers? Perhaps the Americans were most advanced in that direction. The technical students in Canada were welcomed by the works over the border, where, after two years, they were transferred to the sales departments, and when they left the works they went away with the idea that no other firm could touch the manufactures of the works concerned.

The Canadians said that if the British wanted their business they must go to them; if they did not go over the Canadians presumed that the British did not wish for their trade. If the volume of business transacted by one British firm was insufficient to warrant a representative proceeding to Canada, several firms should co-operate in appointing a joint agent to justify his devoting his whole time and attention to the business. That, again, presented difficulties from the standpoint of how the overhead expenses of running the office were to be paid by the firms using the agent, and a further obstacle existed where the agent was dealing with machinery and equipment, a business which ran into a considerable sum of money. The agent might be a good one who could secure a fair number of orders, but a limited capital of £15,000 or £20,000 only covered a few transactions in machinery.

Mr. Wickes, in conclusion, referred in detail to the suggested establishment in London of a general commercial staff—a Ministry of Commerce—and he suggested that the Admiralty, the War Office, the India office, the Crown Agents for the Colonies, &c., should come to some arrangement whereby periodical meetings could be held at which the Board of Trade might offer its experience, and at which an interchange of views might take place in regard to the purchases of materials and stores by these departments, the requirements in which were enormous. The proceedings concluded with a resolution urging on the Government and the Board of Trade the desirability of increasing the number of Trade Commissioners and pointing out the advantage to British trade to be derived from the frequent interchange of views between these representatives and business men in this country.

We trust that this expression of opinion will receive attention in the proper quarter. It seems to us that in any affort that the Government and the Board of Trade make to modernise and increase the efficiency of their relations to the trade of this country, they have at hand a particularly strong man in Mr. Hamilton Wickes.

Until the beginning of this week the Lead. Lead Market had held up pretty well, although the best point reached in the latter portion of last month had not been fully sustained. There had been a pretty fair inquiry which, in conjunction with the comparatively restricted offerings, partly owing to the stiff attitude of American holders, and to the shortage of tonnage available for moving lead from Spain to centres of demand, contributed to prevent much of a relapse in prices on the London market, but this has given place to a reluctant attitude on the part of buyers, and as soon as sellers showed a determination to dispose of a portion of their holdings there was a very rapid relapse. There had been a considerable amount of lead held by speculators, and this has been rather forced for sale, while the decline was accentuated on Monday, when English desilverisers came into the market. Although these interests did nothing in the way of pushing things unduly, they found it impossible to find buyers except at a very sharp reduction, and the decline compared with the previous trading was not far short of £2 a ton. It would appear that the English refiners had been receiving larger quantities of silver-lead from abroad, and that buyers seized the opportunity of standing out from the market in order to establish a considerably lower level of prices. Under these circumstances the present tendency of the market is one of some uncertainty, and with hardly anything doing for export the tendency will probably remain doubtful until some fresh feature develops. Meantime, however, the price has steadied and a fair upward reaction has been seen, while the feeling is more confident again.

It is a matter of considerable gratification that the absurd premium which was latterly established upon near

deliveries should have been cut down to such an extent as has been the case. The reduction in the premium was unquestionably due in part to the refusal of the Government to issue export permits. As soon as it became known that there were instances in which shipping permits had been refused, the market took on an easier tendency, and there can be no doubt that in any further upward manipulation the prime movers will have to reckon upon possible Government action tending to bring about, as far as possible, normal conditions. High premiums on early deliveries are against the best interests of the trade, and this is so in all cases. The frank recognition by the authorities of the position in this respect should act as a strict deterrent upon undue manipulation, and should have salutary effect in directions other than the lead market. It is expected that further heavy buying on Russian account cannot be long deferred, but the relative sluggishness experienced in this direction for some weeks past has been the cause of no little disappointment.

Restraint of Trade.

We have upon several occasions called attention to what is known as the "covenant in restraint of trade" which

is to be found in so many contracts of service. For his own protection, the employer is often compelled to demand that those who enter into his service, and incidentally learn the secrets of his business, shall, for a time after leaving his employment, refrain from carrying on a similar business, or from entering the service of those who do so. Primâ facie, all such covenants are void as being in restraint of trade, and therefore contrary to public policy; but a long series of decisions in the Courts has modified the law so as to render enforceable, covenants which are reasonably necessary for the protection of the employer and not unduly harsh to the employe. An example of the class of case which often comes before the Courts is to be found in Herbert Morris r. Saxelby, which has been reported during its several stages in our pages, and was fully given in the Times of April 1st.

The plaintiffs were engaged in the manufacture of very special forms of machinery, including pulley-blocks, runways, and travelling cranes. Their business was a leading one in the United Kingdom in this class of machinery and extended over a large part of the United Kingdom. In March, 1911, the defendant entered into an agreement under which his salary was £3 17s. 6d. a week, and his engagement for two years certain. By Clause 7 of the agreement he covenanted with the plaintiffs that he would not—

At any time during a period of seven years from the date of his ceasing to be employed by the company, whether under this agreement or otherwise howsoever, either in the United Kingdom of Great Britain or (sic) Ireland, carry on, either as principal, agent, servant, or otherwise, alone or jointly, or in connection with any other person, firm, or company, or be concerned or assist, directly or indirectly, whether for reward or otherwise, in the sale or manufacture of pulley-blocks, hand overhead runways, electric overhead runways, hand overhead travelling cranes, or any part thereof, or be concerned or assist as aforesaid in any business connected with such sale or manufacture.

On leaving the plaintiffs'employment the defendant at once went into the employment of Messrs. Derome, the French agents of the plaintiffs, but in March, 1914, he entered the service of Messrs. Vaughan & Son, Ltd., Manchester, who were the principal competitors of the plaintiffs in the manufacture of some of the articles mentioned in the above Clause 7. Thereupon the plaintiffs brought these proceedings, claiming an injunction against the defendant substantially in the terms of this clause.

In these circumstances, Mr. Justice Sargant held that while the covenant was not unreasonable from the plaintiffs' point of view inasmuch as it was necessary for the purposes of their business, it would be wrong to enforce it against the defendant, as it would deprive him and the public of the benefit of the skill and experience which he had acquired while in the plaintiffs' employment, and prevent him using his knowledge. By a majority the Court of Appeal upheld this decision. The Master of the Rolls pointed out that restrictive covenants are usual in three cases:—(i) Where a trade secret requires protection; (ii) where the goodwill of a business is sold; (iii) where the liberty of a former employe is to be restricted. While they must be construed

very strictly in (i) and possibly also in (ii) a greater freedom is to be exercised in (iii). In applying the older decisions to the facts of the present case, the Court was animated by the desire to prevent the defendant being deprived of the advantage of all his previously-acquired knowledge, and to relieve him from having to start the world afresh. The case emphasises the importance of consulting a lawyer before any document containing a restrictive covenant is signed.

Wire Manufacturers and Development of the Overseas Trade.

British manufacturing houses, thus accounting in a large measure for the extreme pressure at present existing among wire manufacturers, &c., in this country, particularly in the copper section.

The neglect of the overseas trade in the past, and the great possibilities of development in this section, which the war has been the means of demonstrating, will doubtless result in a far wider outlook being taken by British wire manufacturers in the near future than has hitherto been the case. Until recently, no attention seems to have been paid to the development of the overseas trade, partly through the continued steadiness of home demands, but more particularly through the failure to appreciate to the full extent the enormous possibilities of the foreign markets.

It is interesting to note that of recent years great developments have taken place in the variety of the commodities shipped from the two great hardware shipping centres, Manchester and Birmingham. few years ago the average Manchester shipping house concerned its-if with little else but the shipment of cotton Nowadays, practically every shipping house in the city has a hardware department, from which is shipped every description of hardware goods. This expansion of trade interests has been materially stimulated by the enterprise of the manufacturers themselves, who, in adopting the most up-to-date methods before placing their propositions before the shipping houses, have succeeded not only in inspiring the buyers to place the new commodity on their selling lists, but in encouraging them personally to supervise also the sending out to agents and travellers abroad the catalogues and samples submitted by the manufacturers. The catalogues, which become indispensable to the shipping house buyer by reason of the enormous amount of time and labour they save him, are usually printed in three languages, English, French and Spanish, and they bear no manufacturers' name; but the brand or trade mark, by which only the native mind identifies the goods, is a feature of great im-The more distinctive and picturesque the brand or trade mark for goods sent, say, to the South American States, India, and most of the British Colonies, the better the prospect of the commodity being distinguished from all others by the native buyers, and consequently enjoying a greater preference.

If the manufacturer can stimulate the interest of the shipper, as he is almost certain to do, to send out his samples and catalogues to the agents and travellers abroad, he has accomplished what 99 competitors out of the 100 who do not supply these catalogues, &c., fail to do, without which enterprise no steady overseas trade can be expected to accrue.

In shipping to countries like Brazil, Mexico, and other such distant markets, it has been found, even by the largest manufacturers, that it is most beneficial to trade with these countries through a local shipper, who has his own agents on the spot to safeguard his interests, whereas the manufacturer, in the majority of cases, instead of receiving a 3 per cent. prompt cash settlement from the shipper, has to wait as long as 8 to 12 months for settlement, and very frequently, after having incurred heavy expenses, never gets his money at all.

# THE CASE FOR THE ELECTRIFICATION OF PORTLAND CEMENT WORKS.

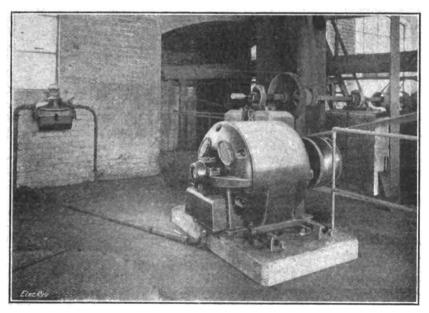

#### BY ERNEST P. HOLLIS.

PORTLAND cement is consumed in increasing quantities every year, and the rapid increase in consumption has induced considerable enterprise into the cement manufacturing world. New cement works are being laid down on every hand, and old ones are being modernised. The prospects for electrification schemes are therefore of the brightest, but the electrical engineer charged with the duty of approaching cement manufacturers with electrification proposals is often severely handicapped by a lack of acquaintance with the conditions obtaining in cement works, and especially the technical processes and terminology of cement manufacture. To the electrical engineer such terms as "kominor," "cylpebs," "silos," "slurry" and "dynamics" come as Greek, and a conversation with a cement works engineer in the vernacular of cement technology would be largely unintelligible to an uninitiated electrical engineer. It goes without saying that, if a cement manufac-turer is to be approached on the electrification question, that electrical engineer will be the more likely to succeed who can converse with him in his own technical language, can understand his processes, and be able to convince the cement engineer that he (the electrical engineer) possesses an inside knowledge of the electrical requirements of a cement works.

Such a knowledge is difficult to gain. Even those electrical engineers who have occasion to visit cement works frequently on business bent gain very little insight into the technicalities of the process. Particularly is this so because the arcana of the cement world

are usually guarded.

Cement Manufacture.—The primary ingredients of cement made by the wet process are clay, chalk and water, a mixture of which is thoroughly ground, then burnt in a kiln, and finally mixed with gypsum and ground again. Although the process wears a

60 H.P. PIPE-VENTILATED MOTOR DRIVING COAL-CRUSHING PLANT.

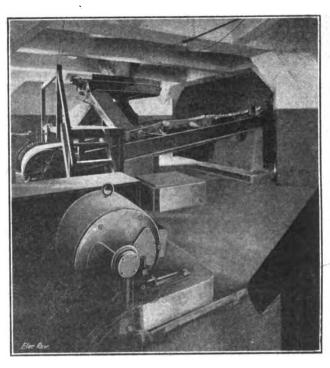

superficial air of simplicity, the technicalities are complicated, and there are very great differences in the qualities of the cements produced by various makers.

There is also a dry process, largely used abroad, which is not dealt with here.

Viewing the process more in detail, it can be divided up for a typical modern cement works into four main stages in which the materials are treated:—

(a) The wet or raw mill.
(b) The mixing pits.
(c) The kiln.
(d) The dry or crushing mill.

In the electrified mill it is possible to make the process completely automatic, i.e., from the time the ingredients of the cement enter the works to the time the final product leaves it, no occasion arises for manual labour. The functions of the employés resolve themselves simply into supervision and main-

15 H.P. PIPE-VENTILATED MOTOR DRIVING BAND ELEVATOR FROM SILO TO KOMINORS.

tenance and no direct labour needs to be applied to the cement throughout the whole course of its manufacture.

That large savings in wages and improvements in the quality of the cement accrue from automatic operation goes without saying, and the elimination

of the human element assures a constancy in quality with the same ingredients that enables very delicate adjustments to be made to improve the operation of the plant.

The Wet or Raw Mill.—The four stages can now be discussed more fully for a typical mill. Naturally the details will vary in particular instances, but the following remarks apply to a large modern works.

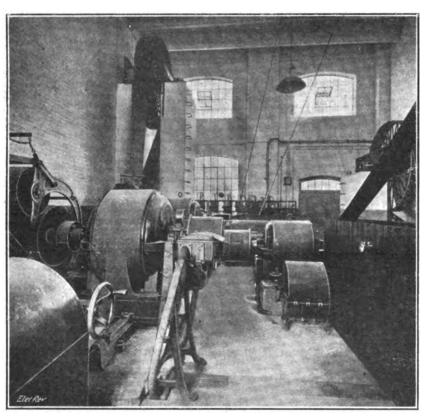

The chalk is tipped from a rail-way-siding—after the consignment has passed the scrutiny of the chemical laboratory—into a chalk intake or hopper, where it is met by a band or bucket elevator and lifted to the top of the building. This building is a strong, well-built brick construction, and has three stories. Arrived at the top of the building, the chalk is dropped into a "silo" or bunker. A word with regard to these silos may be opportune here.

In many stages in the cement-making process the silos are met, and their function is purely one of storage. The cement process is a continuous one, and a machine is never shut down except under compulsion. Compelling circumstances, however, arise; the mills need to be "topped up" with the grinding stones or boulders every week; the lining of the rotary kiln needs to be repaired; and so forth. Were there no storage available the stoppage of a single item of the plant would mean the shutting down of the complete unit. To preclude such a happening, arrangements are made for the storage of the mate-

rial at a number of points. If the wet mills are shut down, the kiln has a stock of slurry to draw upon; if the kiln be cut out of operation, the wet mills can still feed into the slurry storage pits, and the dry crushers can still draw upon the silos for clinkers.

Reverting to the silos, these have at their bottom an outlet which may be closed by a slide. From here the chalk is conveyed by a band conveyor, and, together with a mixture of clay and water, which has been previously mixed in a separate clay mill, it is discharged into the first of the rolling mills. At this stage the mixture is designated "raw slurry."

The mills usually employed are three in number, (a) the kominor, (b) the tube mill, and (c) the cylpebs. There are other types, but the three mentioned are mostly met in modern practice. The mills are usually installed in pairs, the raw slurry passing through them in the order named. A close understanding of the operation of these mills is important, for no matter what be the material to be ground—slurry, dry cement or coal—it usually goes through exactly the same process for crushing.

TIPE-VENTILATED MOTORS OF 250, 175 AND 60 H.P. DRIVING THE WET MILL.

The kominor mill takes the form of a large drum, and contains heavy steel balls about 6in. in diameter. From the kominor the slurry passes on to the tube mill by gravity. The tube mill consists of a long tube some 15ft. long, 4 or 5ft. in diameter, and contains pebbles and boulders. Again by gravity the slurry passes on to the cylpebs wherein the grinding process is finished. These cylpebs are drums some 12ft. in diameter, and containing about 12 tons of short lengths of iron bar about §in. diameter. After leaving the cylpebs the slurry is kept continually stirred in pits, from which it is drawn by the aid of slurry pumps up to the set of pits in which the mixing process proper is conducted.

Mixing Pits.—On emerging from the wet mill, the slurry, prior to its burning, undergoes a thorough mixing in order to secure a uniformity of consistency that is beyond suspicion. It is not sent into the main mixing pits, but goes first into the "correction basin" or "doctor pits." These pits derive their appellation from the fact that at this point the works chemist takes a lively interest in the composition of the slurry. His analysis lays bare any discrepancy in the constituents, which is remedied immediately in

the wet mill. The next lot of slurry that comes along contains a preponderance of that constituent which is missing in the one under analysis, and the mixing of the two remedies the defect.

of the two remedies the defect.

A mixing pit consists of a number of large concrete basins containing stirrers. Each stirrer is composed of a number of long arms radiating horizontally from a central rotating spindle, which rotates Between the several pits at a slow speed. is an intricate system of locks and sluices, so that any defective batch of slurry contained at that moment in the correction basin can be passed into one of the mixing pits and held up there until what may be called an antidote batch arrives. Between the correction basin and the main pits the slurry is transported by means of inclined screws revolving in concrete troughs. By these the slurry is screwed from one point to another. The mixing process is rather a long one, so that the pits have to have a comparatively large capacity. On the completion of the mixing process the slurry is pumped up and discharged into the rotary kiln

Rotary Kiln .-- The introduction of the rotary kiln, in addition to effecting an immense saving of time over the older burning methods, has opened a further field for the application of electrical power in a cement works. The kiln consists of a long tube. which may be 220ft, in length in the largest size and about 12ft. in diameter at the burning end. The smaller kilns are usually about half this length. It is slightly inclined so that the slurry entering at the top can descend by gravity, while the hot gases originating from the fire at the lower end pass upwards, and ultimately emerge into the atmosphere through a tall brick stack. The slurry and gases therefore pass in opposite directions. The rotating motion of the kiln ensures that every opportunity is given to the slurry to come in contact with the gases. The product of the kiln is a hard substance fairly small pieces termed clinker.

One cannot do other than admire the rotary kiln as an example of engineering construction. The stresses induced by the great length must be large, but added to this are the torsional stresses due to

driving, to say nothing of those of expansion and contraction due to heating. It is agreeable to find that the design of these kilns has reached such a pitch that no trouble at all is experienced with them.

The kilns are only driven at one point; in the larger kilns this point is at the centre. The speed of rotation is not more than I R.P.M., the kiln being driven through belting and gearing, which is often capable of giving two speeds.

capable of giving two speeds.

For the purpose of driving, a toothed rim is bolted on to the kiln which gears with the wheels. Naturally the latter must have very wide teeth in order to engage with those of the kiln-wheel when running at any temperature, the expansion and contraction being, of course, considerable.

After leaving the kiln, the clinker is passed on to a cooler which works in conjunction with the kiln. It consists of a miniature kiln with the exception that, instead of a fire, a current of cold fan-propelled air is passed through it for cooling the clinker.

As has been said, the kiln is fired by pulverised coal. This coal is blown into the kiln with a blast of air and gives a very high temperature, often attaining 3,000 degrees F. The coal is usually pul-

verised by a grinding plant exactly similar in nature to that used for the grinding of the cement. There are kominors, tube mills and cylpebs which grind the coal down to a very fine state.

A kiln of the large size described has an output of about 7.5 tons of clinker per hour, and rather less than one ton of coal is burnt per ton of clinker.

Dry or Cement Mills.—Leaving the rotary kiln and its cooler, the clinker, after being sprayed with water to "kill" any remaining uncombined line, next proceeds to the dry or cement mills, the most noteworthy characteristic of which is the immense amount of fine dust with which the atmosphere is laden and the floors covered. The transportation of the clinker from the cooler to the silos is done by a conveying plant

In the ordinary way the clinker is drawn from the bottom of the silo into the crushing mills, which are an exact replica of the wet mills. Sometimes a kind of mill working on very much the same principle as the pug mills for mortar, which are commonplace to all building operations, takes the place of the kominor. Before passing into the kominor the clinker is mixed with gypsum, and the two are ground together. The final product passes on to the sacking machines which fill the sacks with cement. These sacks, by the way, have to be dried before being filled with cement, and for this purpose are dried by a current of warm air propelled by small electrically-driven fans.

Economy of Electric Drive.—The design of the modern works, scattered as it is over a large area with numerous points at which power needs to be applied, makes electrification eminently desirable. The introduction of the rotary kiln has done a great deal towards making electrification inevitable, for with its arrival the process could be made completely automatic. Generally speaking, the steam drive from a central point would be so inefficient as to make modern cement works operated on this principle commercially impossible. Even when steam is generated at a central point and distributed in an efficient manner to the various mills, the large number of small steam engines, which cannot remain unattended, involve a heavy prime cost and running charges, and raise the operating figures to a far higher point than those of an electrically-driven mill.

In addition to economies in the cost of power which are to be expected for the usual reasons from the installation of electrical plant, electricity offers in addition an easy method of determining the efficiency of the many mills, the power consumption of which up to the present has been shrouded in mystery. Taking as an example the tube mills, it has been found that one of these which had been taking 160 H.P. prior to electrification could have its power consumption, with the same quality of slurry, reduced to 112 H.P. by experimenting with different heights of pebbles in the mill. With steam plant it was impossible to obtain any accurate measurement which could be taken as an authoritative criterion of Naturally, in a the power required by the mill. cement works where dust is so prevalent, line shafting, which is inevitable in great lengths with steam plant, is to be avoided at all costs, and the individual electric drive permits considerable economy in this direction.

A great many of the operations in the cement works involve the transport of material from one point to another by belt conveyers, screws, and other methods. For this class of driving, the electric motor is invaluable, as it can be installed in out of the way places in which it would be extremely difficult to utilise a mechanical drive. A large number of electrically-driven cement works are now in operation, and satisfactory testimonials can be obtained from these works which will convince any cement works engineer in doubt as to the efficiency and convenience of the electric drive.

# WIRELESS CONTROL OF PUBLIC CLOCKS.

#### BY ALFRED E. BALL.

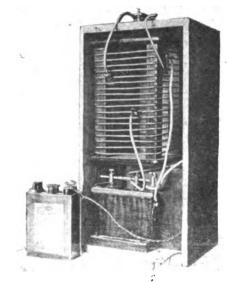

RADIOGRAPHIC waves have proved of great service in the distribution of time over extensive areas, and will doubtless be pressed into the service of the horologist in many other ways; one of the most useful will, in the writer's opinion, be the wireless control, or rather supervision, of public clocks.

The scheme advocated, which has been put to a practical test by the writer, consists briefly in fitting each of the main public clocks in a town with a small wireless transmitting set, which would be operated periodically by the clock at definite times, and the installing of an official wireless receiving station, at which the various clocks would be checked daily. By means of this system each public clock would report its time-keeping, and in the case of any clock having an error greater than a certain small pre-determined value, steps could be taken at once to have it corrected.

The working of the scheme would be as follows:—
It is assumed that eight of the principal clocks of a town have been fitted with the automatic transmitting apparatus, which will be described later.

ting apparatus, which will be described later.
At the sound of an "attention" bell (arranged to ring shortly before 10 a.m.), the person deputed to "listen in" at the wireless receiving station (which we will assume, is installed at the Town Hall) receives the Paris time signal, from which he checks a standard clock, which should be provided with a seconds hand.

The error of the standard clock is duly noted in the clock rate book. He then moves the tuning slides of his receiving instrument to a position suitable for the reception of a 50-metre wave length which is marked on the coil, and listens for clock No. 1, which has been arranged to send its signal at 10.1 a.m. As soon as he has moved his slides to the

F1G. 1.

required position, he hears clock No. I sending a series of short "buzzes," which continue for, approximately, a minute, and terminate precisely when that clock shows IO hours I minute a.m. By keeping his eye on the seconds hand of his standard clock while listening, he is able to note the error of clock No. I to a second, and this error is duly noted in the rate book in a space provided against the number of the clock.

No. 2 clock does not commence sending its signal until 10 hours 1 minute 40 seconds. The longer time has been given to clock No. 1 to give the operator ample time to tune in sharply and so get good signals. At 10 hours 2 minutes by No. 2 clock it signals its time by its last "buzz," and its error is also noted in the rate book.

Similarly the remaining five clocks are checked, the entire process occupying eight minutes, or, including the taking of the Paris time-signal, eleven minutes.

Means would be provided to enable the different clocks to be identified. The intervals of 40 seconds between the signals should be sufficient to prevent overlapping, as no public clock should have such an error. The signals can be repeated by the clocks at, say, 3 p.m., so that supervision may be exercised twice daily.

The writer has proved that, for the purpose in view. the wireless aerial may be quite unobtrusive, the apparatus simple and inexpensive, and the power

small.

Fig. 1 is a photograph of the transmitting apparatus employed by the writer. This is a simple affair, contained in a box measuring 20 in. × 12 in. × 8 in., and is operated by a small 4-volt ignition accumulator which would last one month or longer with one charge.

Each turret clock to be supervised would require the following:

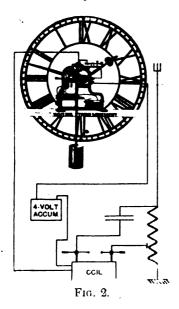

(a) A transmitting apparatus as shown in fig. 1.

(b) Contacts fitted to the clock movement to break contact at a certain definite pre-arranged time.
(c) An aerial, which may be of an unobtrusive

pattern.

(d) An "earth" connection, which may be the lightning conductor or a water pipe.

The connections of the apparatus to the contacts mentioned and to the aerial and "earth" are shown diagrammatically in fig. 2; incidentally, the movement shown is an electric "waiting-train" turret movement-now largely used for turret clocks-of which the writer is co-patentee with the makers,

Messrs. Gent & Co., Ltd., of Leicester. The aerial in practice need only be a single wire; the one used by the writer in his experiments passed unnoticed up to the time of its removal on the outbreak of the war, and its length was 40ft. approximately. The separate "buzzes" are obtained by means of a contact operated by the pendulum at each swing, and the sudden cessation of the "buzzes" is produced by a contact in series therewith which is broken by falling off a cam fixed to, say, the centre wheel. In the case of a "waiting-train" movement, the spring which makes contact with the pendulum may be a fixed one. and may contact idly when not in operation, because the "interference" could not affect the timekeeping but in the case of a mechanical movement this spring may be lifted out of the way by a cam when not in use, or brought into action by an electro-magnet only when required.

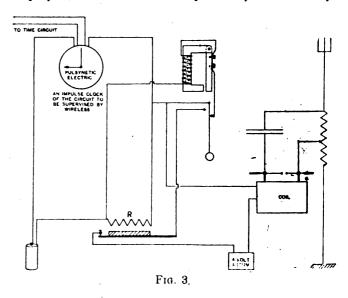

In the case of a striking turret clock the lifting cams (or pins), or the lifting lever, could be utilised for making the necessary contacts, the last "buzz

in this instance indicating the last blow of the hour struck. In checking the time of such a clock from the last blow, allowance would be made for its striking rate; thus—if the intervals were 3 seconds, the clock's actual time would be 27 seconds in advance of the last "buzz." This method of "contacting" assures that the striking is in order, as well as that the clock is to time. A town which desires to be "well-timed" should decide that, should any of its supervised clocks signal an error of more than 10 seconds, its custodian should be instructed to correct it forthwith.

The transmitting set shown in fig. I would be, in practice, completely enclosed in a dust-tight box, and as the only moving part would be the contact-breaker of the coil, little or no attention would be needed. In the event of the contact-breaker being out of adjustment, this would be indicated at the receiving station.

The writer has designed and made an instrument to enable a system of impulse clocks to signal its time-keeping to the receiving station, and therefore be supervised. This instrument consists essentially of a short and light pendulum, which is arranged to operate after the manner of a slow-ringing electric bell. One dry cell operates it, and its circuit is closed at pre-arranged times by contacts fitted to one of the impulse clocks in the circuit. The clock employed by the writer for the purpose was one made by his firm for ringing bells in a factory for the starting and stopping of work. The contact is closed for half a minute, and, in vibrating, the pendulum runs full tilt into contact with a spring at the end of each swing. thereby closing the circuit of the induction coil and producing a series of timed "buzzes" at the receiving station. By using pendulums of varying periodicities, different clock installations could be readily identified.

Fig. 3 shows diagrammatically the connections employed, which are self-explanatory. The relay

shown at R is necessary to break the primary circuit of the induction coil precisely at the end of the half-minute, and so terminate the "buzzes," because the pendulum, by its inertia, continues to swing and so touch the contact spring after the clock contact is broken.

Identification of individual turret clocks could be secured in many ways. First, the varying pendulum lengths could be taken advantage of when pendulum contacts are used, turret clock pendulums varying from I seconds beat up to 2 seconds or more in steps of \$\frac{1}{2}\$ second, and so the frequency of the "buzzes" heard would enable the clock to be identihed, should it be considerably out of position on the schedule. Also, in the case of "striking" contacts, the frequency of the "blows," or rather "buzzes," would be a means of identification. Coupled with the foregoing features, a variation in the character of

the note can be employed by variations in the design

of the spark-gap and contact-breaker.

The object of advocating the employment of the short wave length of 50 metres and small aerials is to ensure that the large commercial stations be not interfered with. Interruption or "jamming" would be possible from local amateurs with untuned apparatus, but, as amateurs usually only display their activity at night, trouble would not be experienced on this score.

Fig. 4 shows the receiving station used by the writer.

Before wireless supervision could be adopted, it would be necessary to get a licence from the Postmaster-General, who would specify the maximum

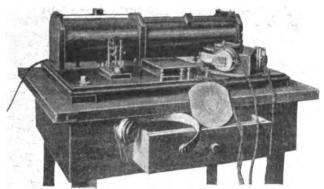

Fig. 4.

wave length which would be permitted, and also the maximum power to be employed. The requirements of this scheme are below the limits usually stipu-

An argument against the adoption of the scheme would be that, in the event of another European war, the scheme would be put out of operation by the suspension of the licence during hostilities. The writer ventures to assert that it will be a "long, long time" before Europe will again be brought under the spell of war.

# NOTES FROM CANADA.

[FROM OUR SPECIAL CORRESPONDENT.]

In Kamloops, B.C., power to spend \$80,000 for hydroelectric work is being sought. Yorkton, Saskatchewan, is noteworthy for the fact that some four years ago the first generator set driven by a Diesel engine in Canada was installed there; a second set, of 500 B.H.P., has recently been put into operation, the first one being only of 150 B.H.P.; provision has been made for three additional 500 B.H.P. sets. In isolated spots out in the West, Diesel oil engines would seem to be very suitable, as coal is very expensive, and under such conditions the advantage of having no stand-by losses for fuel is plain. fuel is plain

Prince Albert, Saskatchewan, has just put into operation recently an automatic telephone system, and in Crystal City, Manitoba, a new telephone company with a capital of \$20,000 has been formed.

Mantoba, a new telephone company with a capital of \$20,000 has been formed.

In Winnipeg. Mr. Leonard Andrews read a paper on "Automatic Electric Lighting Plants" before the Electrical Section of the Canadian Society of Civil Engineers a few weeks ago. This city has almost 40,000 H.P. installed in generating plant and another 5,000 kw. machine is being erected now. The station output is still growing, in spite of war conditions. The last two completed turbines (water) were tested a little while ago after a 30-day continuous run. The makers had guaranteed 6,800 H.P. with a net head of 45 ft.; actually it is possible to obtain 7,200 H.P. with 80 per cent. gate opening under a head of 46 ft.

Several fresh places in Ontario have passed by-laws in favour of obtaining power from the Hydro Electric Power Commission of Ontario, and the farmers in various districts are becoming keenly interested in the possibilities of electricity on the farm as already applied by the Commission in a number of cases.

The agitation in favour of the so-called "hydro radials" (electric railways to be owned by the people, built and run by the H.E.P.C.) seems to be as strong as ever. A deputation representing many municipalities went to Ottawa a few days ago to ask for a Government subsidy, but owing to the war it was found impossible to get anything from the Dominion

it was found impossible to get anything from the Dominion

Government; an attempt is, however, to be made very soon to obtain a grant from the Provincial Government. In view of the enormous benefit to the community at large which, it is practically certain, would result from the construction of such lines, it is to be hoped that the deputation will meet with better success from the latter Government, particularly as it is more directly concerned than is the Government of Canada. The Provincial Government has just given the Commission powers enabling them to take over any electric railway in the Province. Tenders will probably be called soon for the installation of cables in certain streets in Montreal, where underground conduit has been laid, and an appropriation of \$550,000 has been voted for additional conduit work.

That there are sometimes other causes operating to militate

\$550,000 has been voted for additional conduit work. That there are sometimes other causes operating to militate against a continuous supply of energy being given from a station driven by water power, besides transmission line troubles during sleet and other storms, is evident from the experience of the Ottawa Light, Heat and Power Co., which had last year to spend an additional \$50,000 on coal owing to a period of exceptionally low water in the Ottawa River. A sleet and wind storm gave the Bell Telephone Co., the Quebec Railway, Light, Heat and Power Co., and the Dorchester Electric Co. a good deal of trouble a short time ago, when wires were brought to the ground and Montreal was without power or electric light for several days.

In spite of the war, the incorporation of new companies.

In spite of the war, the incorporation of new companies, particularly electrical ones, seems to go on much as usual. At the present time most engineering concerns appear to be taking up the manufacture of shells, large orders for which have been placed by the Government with very many firms; this is a good thing, as in many cases there is little or no other work in hand.

There are not many large steam generating stations in the

other work in hand.

There are not many large steam generating stations in the portion of Ontario surrounding Niagara Falls, but the Dominion Power and Transmission Co., of Hamilton, is building a station designed for an ultimate capacity of 75,000 kw. Although one of the primary reasons for constructing this plant is to ensure continuity of supply, it is noteworthy that the steam plant is designed for continuous operation with a high fuel economy, conditions which add very considerably to the cost of a plant designed merely for stand-by purposes.

According to a statement emanating from the Department of Inland Revenue at Ottawa, Canada exports practically as much electrical energy as she makes use of herself; the figures for exported power and that used in the Dominion are:

Export.

Export. 772,597,049 кw.н. Home use. ... ... ... 770,867,048 кw.н. These figures are for the fiscal year ending March 31st, 1914.

# INDIAN NOTES.

[FROM OUR SPECIAL CORRESPONDENT.]

Bombay Mint.—The plant in the Mint is to be shortly converted to electric drive and Captain Willis, R.E., is returning to Bombay to deal specially with this. He has been in control of the Calcutta Mint for some time back, where electric drive has been very successfully in operation for several years. The plant was provided by the G.E. Co., through their Indian agents, Messrs. Octavius Steele & Co., and has given extreme satisfaction.

extreme satisfaction.

Calcutta Port Trust.—The installation of Excello are lamps in and around the docks and jetties of the Trust is one of the finest in India; but for the supply of carbons for the ensuing year—about 130,000 pairs—the Commissioners are in a quandary. As usual, tenders were invited early in January, 1915, but no satisfactory estimates were put forward; no firm would bind itself by the very strict conditions of supply required, and prices put forward were about double those of the previous years. It is believed, however, that a compromise has been effected and a tender has been accepted without binding penalties. If a satisfactory supply of carbons cannot be ensured the only alternative will be to substitute half-watt lamps of high candle-power later on.

be ensured the only alternative will be to substitute half-watt lamps of high candle-power later on.

Electrical Engineer Volunteers.—Probably 90 per cent. of the European electrical men in India are volunteers of one sort or another, although there are very few, if any, on active service. The Electrical Company of the Calcutta Port Defence Volunteers have been doing good work for months back under the able direction of Captain Stovold, of the B.I.S.N. Co., by way of manning the searchlights in the forts on the Hugh. Their work has slacked off considerably, however, since the Emden got her quietus; but while this aggressive little gun boat was roving about Indian waters the engineers, electrical and others, in charge of port and coast searchlights had a particularly anxious and trying time. Madras was without a port searchlight when the city was shelled by the Emden.

The Secretary of the Institution of Electrical Engineers sent out post-card inquiries some time ago asking for names of

out post-card inquiries some time ago asking for names of members on military service. Some misapprehension exists as to whether volunteers in active training are considered on active service or not. The majority of men interested favour the idea that the names of men only actively engaged on military operations either in Africa or Earpt or the Per important of the property of the Per important of the property of the Per important of the property of the Per important of the property of the Per important of the property of the Per important of the property of the Per important of the property of the Per important of the property of the Per important of the property of the Per important of the property of the Per important of the property of the Per important of the property of the Per important of the property of the Per important of the property of the Per important of the property of the Per important of the property of the Per important of the property of the Per important of the property of the Per important of the property of the Per important of the property of the Per important of the property of the Per important of the property of the Per important of the property of the Per important of the property of the Per important of the property of the Per important of the property of the Per important of the property of the Per important of the property of the Per important of the property of the Per important of the property of the Per important of the property of the Per important of the property of the Per important of the property of the Per important of the property of the Per important of the property of the Per important of the property of the Per important of the property of the Per important of the property of the Per important of the property of the Per important of the property of the Per important of the property of the Per important of the property of the Per important of the property of the Per important of the property of the Per important of the property of the Per important of the property of t Gulf and elsewhere were required.

Ban Kipore.—This new capital of the recently constituted province of Behar and Orissa is growing rapidly in size and importance. Messrs. Gifkins & Co. are said to have got the concession for the electric lighting of the city and cantonments. Government House has already got its own installation, and the High Court and Post Office are both being installed with electric lights, fans, and lifts. Contractors are asking one another how it is that no tenders were called for before it was decided to give the work to a firm of Calcutta builders who are managing agents for a well-known electrical heme firm. Such, however, is the way things are often done in India, and this very reprehensible practice is one which is growing, and one which should have the attention of the in India, and this very reprehensible practice is one which is growing, and one which should have the attention of the higher P.W.D. authorities. The amount of the contract in this particular case which was given away without asking for competitive tenders was approximately £5.000.

War Effects.—From the point of view of electrical engineering business, the war has made but slight difference up to the present. Contractors have their hands fairly full and there have been very few instances of firms diminishing their staff or work man because of shortness of work. In fact electrical

or working because of shortness of work. In fact electrical firms may be said to be more busy this year than for some time, and inquiries from Government P.W.D. and from military works departments have been very brisk indeed. Probtary works departments have been very brisk indeed. Probably, however, a period of slackness may set in from April, 1915, as Government budgets run from April to the following March, and it is usual to expect a rush of inquiries and orders so that amounts previously budgetted may not lapse. As the current budget was passed in pre-war days and was fairly liberal, P.W.D. engineers are able to put through anticipated works. In the face of things at present, the coming Indian financial year is almost sure to be barren of important electrical or other works, which are not an absolute necessity, and trical or other works which are not an absolute necessity, and hence contractors who depend much on Government contracts can scarcely look forward to the year 1915-1916 as one with a

#### CORRESPONDENCE.

Letters received by us after 5 P.M. ON TUESDAY cannot appear until the following week. Correspondents should forward their communi-cations at the earliest possible moment. No letter can be published unless we have the writer's name and address in our possession.

#### Electric Vehicles.

A propos of your recent article on this subject, and of all current discussion, I failed to observe any suggestions and remarks regarding the application to that unostentatious vehicle known as the "Steam Roller." It would be interesting to hear of any investigation, municipal or otherwise, in this direction, and the conclusion sions derived therefrom.

Running and initial cost, also low radius of operation, may be points of discussion, but I think we can safely anticipate lower depreciation charges, and here at last is an instance in which the weight of the modern lead battery would stand as a decided advantage to the designer.

L. G. Toplis.

Glasgew, April 12th, 1915.

#### Electric Cooking.

In a leaderette in your issue of March 19th you refer to my remarks at the I.E.E. on Mr. Cooper's paper, and I think your observations call for a reply from me. In stating that the matter observations call for a reply from me. In stating that the matter goes beyond the scope of the Sub-Committee of the Engineering Standards Committee, of which I am chairman, you are, I think, unaware of the constitution of the particular Sub-Committee or "panel" dealing with this matter. On this panel are representatives of the I.M.E.A., Public Supply Companies, the B.E.A.M.A., the Electrical Contractors' Association, and the fire offices, so that it is difficult to see how it can well be more representative. I altogram on what grounds you apparently advocate altogether fail to grasp on what grounds you apparently advocate the setting up of the I.M E.A. as the proper authority to deal with the question; I should think that the supply companies, among which are to be found some of the most active workers in connection with electrical cooking, would have something to say on this matter. You are quite mistaken in supposing that the panel are in the least degree inclined to let the matter rest; on the contrary, they are actively at work on it, and they have the cordial co-operation of each one of the Associations which I have enumerated above

Like most questions of standardisation, that of electric cooking apparatus lends itself to light and airy generalisations; but it is only those who have applied themselves to the actual work of evolving definite standards who apppreciate the real difficulties encountered.

C. H. Wordingham.

London, April 5th, 1915.

We think it can scarcely be denied that, as the result of its extensive experience, and the fact that the great majority of our electricity supply undertakings are under municipal control, the I.M.E.A. is the most competent body to evolve a scheme which will enable consumers generally to obtain electric cooking apparatus on reasonable terms.

We fully appreciate the efforts that are being made by the Standards Sub-Committee, of which Mr. Wordingham is the chair-

man, and if they result in the consumer obtaining standardised and cheaper apparatus, so much the better. But it will be remembered that Mr. Wordingham, in discussing Mr. Cooper's paper, said with regard to the Sub-Committee that there seemed to be a great diversity of opinion as to the desirability of any standardisation whatever in connection with electric cooking apparatus, and that the manufacturers were not very eager for standardisation, from which we may justifiably assume that progress will not be very

On the other hand, Mr. Wordingham said he was strongly of opinion that there were certain things which might well be standardised, and in this we cordially agree with him.

Whether a representative Sub-Committee of the Engineering Standards Committee or a single-minded Committee of the I.M. E.A. brings about the desired result is immaterial, so long as that result is attained.—Eds. Elec. Rev.]

#### Preferential Rates.

Referring to your leading article in the current issue of the ELECTRICAL REVIEW re "Preferential Rates," I should like it to be distinctly understood that it is not I, as the acting engineer and manager, that will not accept photographic work at the lowest possible price. I am out for all the day load I can get, at lowest possible price. I am out for all the day load I can get, at the lowest remunerative price, and what is more, I am getting it, for, as a matter of fact, our output for the past four weeks has been greater than for the corresponding four weeks in any year since the commencement of the undertaking, notwithstanding the fact that the Shop Hours Act has recently been put into force here, and the licensed premises are closed at 9 p.m. instead of 11 p.m. as formerly. Moreover, Ilkeston is not a town which is being blessed with war orders.

#### G. H. Browne,

Acting Engineer and Manager.

Ilkeston Tramways and Electricity Department, April 10th, 1915.

[We hope we did not convey the impression that the engineer was in any way responsible for the trouble at Ilkeston; our previous report indicated that the Committee was divided on the point. We congratulate Mr. Browne on his progressive policy, with which we are heartly in sympathy.—Eds. Elec. Rev.]

# Water Heating by Electricity.

In view of the publication in your columns last week of a letter from Mr. George Wilkinson, in which he says that the Journal of Gas Lighting "grossly misrepresented" his recent statements on the subject of electric water heating, I shall be glad if you will kindly publish in your next issue the editorial note which was attached to Mr. Wilkinson's letter when it appeared in our columns

#### The Editor,

Journal of Gas Lighting.

London, E.C., April 9th, 1915.

[In the note referred to, Mr. Wilkinson is described as "uncharitable and thin-skinned," and the reports of his remarks in the electrical Press are quoted in support of our contemporary's criticism. We do not consider the matter of sufficient interest to reproduce the lengthy note in full.—Eds. Elec. Rev.]

# ELECTRICITY EXTENSIONS AT CARLISLE.

THE municipal supply of electricity in Carlisle dates from 1899, when the original scheme, costing some £80,000, which was installed under the direction of Prof. Kennedy, was opened.

From time to time extensions have been carried out on the

From time to time extensions have been carried out on the direct-current system, but within the last year or two, owing to the extended distribution in prospect and the growth of the power load, and the fact that the next plant required would be of the high-speed turbine type, it was decided to introduce three-phase alternating-current supply, and to meet immediate requirements by installing two motor-generators to supply beyond the economical limits of the original direct-current system. This initial scheme was followed by a more comprehensive one, involving loars of £33,240 for plant and £6,000 for mains and recognitations the of £23,940 for plant and £6,000 for mains, and necessitating the of £25,940 for plant and £6,000 for mains, and necessitating the extension of the engine room and provision of a 1,250-kw. turboalternator, with surface condenser and wet air filter, two 600-kw. totary converters, H.T. and L.T. switchgear, circulating water p ping, &c., a new boiler, and additions to the lighting battery. All the available building space has now been covered, and space is provided for two additional 1,250-kw. turbine sets, while foundations have been laid down for a fourth water-tube boiler.

The station now affords accommodation for generating plant sufficient for some years to come, and the boiler power can be increased by substituting water-tube boilers for the older Lancs-shire boilers; the only difficulty appears to be a possible shortage of cooling water for condensing in the summer, when the adjacent

River Caldew is very low.

In 1911 the Council was empowered to supply any place within two miles from the centre of the city, and in 1914 a further special order was made allowing supply to certain houses in the Scotby district; the Stanwix area has been changed over from direct to

alternating supply, and all new large power consumers are to be supplied on this system.

The principal features of the new plant are as follows:—
The turbo-alternator was supplied by the Oerlikon Co., and is of the Rateau type, running at 3,000 B.P.M., and of 1,250 kw. capacity, for supplying three-phase 50-cycle 3,000/3,300-volt current. A steam-driven stand-by oil pump is provided for lubrication purposes at starting, the ordinary pump for this and for

hausting to the atmosphere. Motor-driven circulating and rotary air pumps are provided, driven from the D.C. bus-bars and arranged for automatic change-over to the battery in case of emergency.

The two 600-KW. rotary converters were supplied by the British Westinghouse Co., and are of the six-phase type running at 750 B,P M. The converters are arranged for direct-current starting only, and are available for giving either direct-current lighting or tra

supply or for running inverted from these supplies and delivering three-phase current.

A special exciter and a synchronous booster are mounted on the shaft of each machine, and each of the latter is supplied through a 660-K.v.A. British Westinghouse

oil-insulated self-cooled transformer.

The new switchgear, which has been supplied by the same firm, is situated on a gallery in a recess on one side of the extended engine room.

The recess backs on to the street, and the H.T. feeder cables are brought direct into the switch oubicles.

The switchgear consists of an operating The switchgear consists of an operating board with panels for two rotaries, two turbines and two feeders, and spare panels for an additional rotary and turbine set; behind are the moulded stone cubicles containing the bus-bars, oil-switches, instrument transformers, &c., the cells being arranged back to back.

The direct-current board for the rotaries is connected to the old switchboard by bare

copper strip, and access to the old switch gallery is also provided.

The cost of the original plant at Carlisle, some £30,000 for 370 kW., was, roughly, £81 per kW.; the completion of the present extension giving a plant carriery of \$320 extension, giving a plant capacity of 3,920 KW., brings the figure down to £33 per KW., and with the further additions provided for,

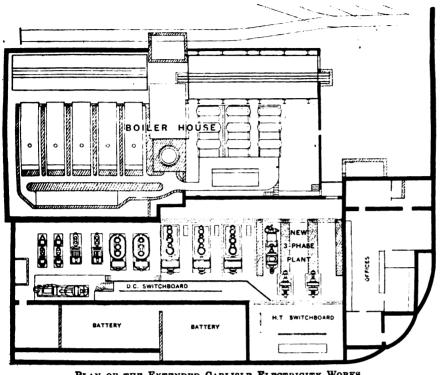

with some 6,420 kw. installed, a further drop to £23½ per kw. will coour.

During the year 1913-14 the undertaking generated 3,759,645 units and sold 3,140,457, of which some 2,360,000 were for power and heating supplies—the latter to over 3,000 H.P. of motors and about 114 kW. of heating and cooking

plant.

There were some 760 consumers, with 55,000 30-watt lamps, connected to the mains; also 57 public arc lamps, and some 290,000 units were supplied for traction purposes.

Ever since the Corporation supply of electricity commenced the revenue has steadily grown, and prior to 1913-14, when there was a small deficit on the working, considerable net profits were earned for many years. It may be noted, however, that during the years 1912-13 and 1913-14 over £5,000 was expended out of revenue on

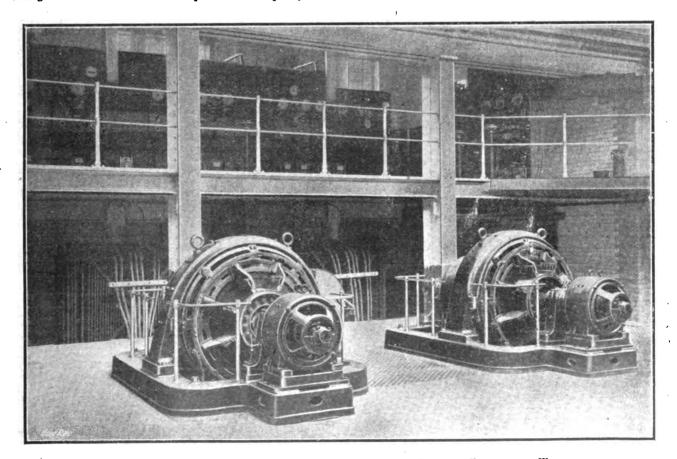

PLAN OF THE EXTENDED CARLISLE ELECTRICITY WORKS.

supplying the oil-controlled relay governor being direct-driven from the turbine shaft.

A separate exciter is direct coupled to the alternator shaft, and

an Oerlikon automatic pressure regulator is mounted on the switchboard.

The wet air filter for the alternator is of the Heenan and Froude type, while the main condenser is of Worthington rectangular pattern; no isolating valve is fitted between it and the turbine, but arrangements have been made for flooding the condenser so as to permit of temporary ex-

WESTINGHOUSE ROTARY CONVERTERS AND H.T. SWITCHGRAB, CARLISLE ELECTRICITY WORKS.

plant and alterations, and the results must be judged accordingly. In conclusion, we are indebted to Mr. F. W. Purse, the City Electrical Engineer, for the particulars here given.

# NEW ELECTRICAL DEVICES, FITTINGS AND PLANT.

# Vacuum Tubes for Telephone Line Protection.

Carbon lightning arresters protect against voltages above 3,000. To protect telegraph and telephone lines against lower voltages, vacuum tubes are used and are of excellent service for protection against voltages above 300. In the *E.T.Z.*, F. Schroeter describes a new form of vacuum tube which

is effective down to 130 volts. The construction is shown in fig. 1. The anode a is an aluminium pin surrounded by a protective tube b. The lower end of the anode a is at tube b. The lower end of the anode a is at a distance of a few millimetres from the cathode c, which is a fused alloy of potassium or sodium. Current is supplied through platinum wires d and e. The tube is filled with helium, neon, argon, or a mixture of these gases at a pressure of from 1 mm. to 3 mm. The life of the tubes is practically unlimited. A tube will withstand thousands of breakdowns without change of its critical voltage. This yacuum tube may be its critical voltage. This vacuum tube may be used with the connections of either fig. 2 or fig. 3. In the first case, the fuse c (operating at about 0.5 amp.) is inserted between the telephone transmission line A and the exchange line B. The vacuum tube D is inserted in an earth connection as shown. If the telephone transmission line should by accident get into contact with an emergy-transmission cable charged to more than 130 volts, or if voltages of this amount should be produced

by induction in the telephone line, an arc is formed in D and the fuse C melts, whereby the exchange line B is separated from the transmission line. In the second arrangement (fig. 3) the telephone transmission line A is separated from the exchange line B by a relay consisting of three parts, E, F, G. The winding E has a high

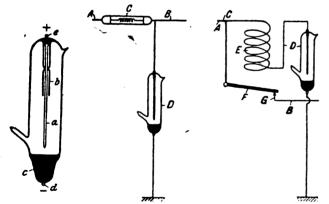

Fig. 1.—Vacuum Tube.

Figs. 2 and 3.—Wiring Connections in Vacuum-Tube Protective System.

resistance, say, 8,000 ohms to 15,000 ohms. When a dangerous voltage occurs, a brush discharge takes place in the vacuum tube of because the high resistance of E prevents the currents reaching an intensity sufficiently high for the evaporation of the cathode which would produce an arc). The current passing through E excites the relay and attacks the armature F, so that the contact between A and B is broken. The interruption lasts as long as the dangerous voltage in A, and stops automatically when the dangerous voltage disappears. By artificial means it is possible to devise vacuum tubes which will operate below 110 volts. For instance, if a is used as the cathode, the surface being covered with a layer of potassium, and a distance of 5 mm. is employed between a and c with a gas mixture of two-thirds neon and one-third helium at a with a gas mixture of two-thirds neon and one-third helium at a total pressure of 2 mm., the break-down E.M.F. is 104 volts. A variation in the width of the vacuum tube has an effect on the critical voltage.-Elec. World.

# Higgs Motors.

In a new list Messes. Higgs Bros., of Sherbourne Road, Balsall Heath, Birmingham, describe a range of standard D.C. motors and generators which they are building. We illustrate the component parts of one of these in fig. 4. The machines are of the protected type, with armature cores of Stalloy, and formerwound coils. The brush-holders are of the sliding-box type, of neat and compact design, and Hoffmann ball-bearings are used throughout. The machines are designed to carry 25 per cent. overload for one hour, and to have a high efficiency; they range in size from 16 H.P. to 25 H.P. An ingenious system of listing

ahunt generators is employed, which enables a purchaser to select a machine to suit his requirements exactly, the output of a given frame being ascertained by multiplying the desired speed by a constant.

The firm has been established about three years, during which time it has turned out upwards of 3,200 motors, and it is now building them at the rate of 2,500 per annum; the very first machines made are interchangeable with those it is supplying to-day in every respect. We understand that the firm has had very few complaints indeed, while the actual number of rejections has been only three. Owing to their using a special material in the

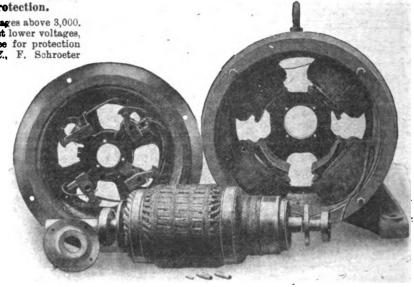

FIG. 4.—COMPONENT PARTS OF HIGGS MOTOR.

manufacture of commutators, the makers have never had a single complaint as regards the mica giving trouble; they have never had a bearing complaint, and have not yet replaced a single bearing, although some of the machines have run as fast as 7,000 B.P.M. They now fit terminal blocks on all their machines, a feature which is not mentioned in the list They regularly have in stock

or progress 300 to 400 motors.

The firm has already had to extend its premises twice, making them three times the original size, and further large extensions

are anticipated in the near future.

# High-Power, High-Pressure Water Rheostat.

In testing modern generating sets, it is frequently desirable to provide a large artificial load, conveniently regulable over a wide range and, particularly when it is desired to test prime mover, generator and transformer as a complete unit, suitable for use in high-pressure circuits. Where pressures of 10,000-20,000 volts or higher are concerned, special care in design is required to secure a reasonably compact rheostat, safe to handle while in use and offering sufficient resistance to provide 1,000-2,000 kW. or greater load. Water rheostats offer the best solution to the problem, long water channels of small section being used to provide resisters of sufficient resistance and current-carrying capacity. Electrodes placed at the points of a triangle in a cooling pond do not form a convenient equipment, and, moreover, the water constitutes almost

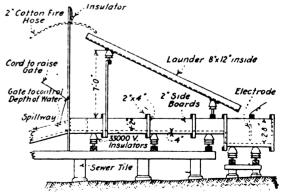

FIG. 5.—WATER RHEOSTAT, SIDE ELEVATION.

a short circuit, unless it be exceptionally pure or the electrodes are very far apart and the pond is shallow. The accompanying illustrations, reproduced from the *Electrical World*, show the construction of a water rheostat found suitable for 250 to 2,500 kW. threephase load at 20,000 volts, using water of exceptionally low specific resistance, viz, 100 to 200 ohms per inch cube. By modifying the proportions of the water channels, adhering to the same general

design, wide load variation can be provided at almost any voltage.

As shown by fig. 6, this rheostat consists electrically of two
Y-connected water circuits, with earthed neutrals at N N and

high potential phase points at A, B, C. Each leg of the rheostat is supplied with water through 50 ft. of two-inch cotton fire hosing, discharging into a steeply inclined open launder as shown in fig. 5. The pipe header supplying the cotton hoses is fed at each end by a two-inch service pipe, and is provided with a separate valve on each outlet. This header is earthed, and the water resistance between it and each of the points A, B, C is about 8,000 ohms, even using water of only 200 ohms per inch cube specific resistance. The converging rheestat troughs are 21 ft. by 18 in. square, ample The converging rheostat troughs are 21 ft. by 18 in. square, ample depth being provided to prevent water boiling over and thus establishing an earth fault. Since the water boils or nearly boils in service, the troughing must be of fairly heavy timber and firmly strapped together. For the same reason, evaporation and consequently changes in density and specific resistance are apt to be high, hence the water supply valves in the pipe header should be kept open as far as possible and load balancing effected by adjusting these valves, and thus the water density and resistance in ing these valves, and thus the water density and resistance in

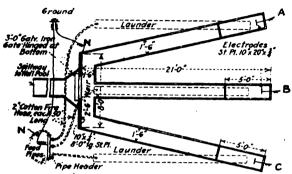

FIG. 6.-WATER RHEOSTAT, PLAN.

each rheostat channel individually. The load as a whole is varied by means of the cord and hinged gate in the discharge weir from the neutral electrode box (see fig. 5). In the rheostat as illustrated, provision is made for load balancing by adjusting the positions of the electrodes A, B, C, but control by regulating the water supply is preferable and perfectly satisfactory. The water hose and flume are insulated; the whole rheostat is carried on \$3,000-volt, pintype insulators, and the only two points needing to be handled during operation (viz., the water valves and discharge gate) are permanently earthed. A cord can be carried from the discharge gate to the meter house test bench, and the water control valves can be located at the same spot. Only a limited supply of water is required; it may be rich in salts and therefore of low specific resistance, and can be used again and again with only the toss due to evaporation. Knowing the resistance of the water, the circuit voltage and the required load, it is easy to calculate the necessary rheostat trough and supply pipe dimensions to meet other conditions than those to which apply the data given in the above illustrations, trations.

Noise and Vibration caused by Electric Plant.

Noise and Vibration caused by Electric Plant.

In the Chancery Division, on Tuesday, before Mr. Justice Eve, the Worksop and Retford Brewery Co., Ltd., moved for an injunction restraining the Worksop Palace, Ltd., from creating a nuisance by the noise and vibration caused by the electric plant on their premises. Mr. Jessel, K.C., said the plaintiffs were the owners of licensed premises adjoining the defendants' property. He understood the motion was now assented to by the defendants, and he asked that it should be treated as the trial of the action and a perpetual injunction granted. Mr. Dighton Pollock, for the defendants, agreed. His Lordship granted a perpetual injunction against the defendants.

#### CUNNINGHAM, LTD.

In the Companies' Winding-up Court, on Tuesday, Mr. Justice Astbury heard the petition of W. T. Henley's Telegraph Works, Ltd., for a compulsory order to wind up Cunningham, Ltd., electricians and electrical engineers. Counsel stated that creditors for considerably over £2,000 had agreed to an arrangement in the matter, but creditors for an amount of about £100 were now standing out. It was possible that they might also agree to the arrangement, and he therefore asked that the petition be allowed to stand over for another week.

Counsel for the opposing creditors consented to the adjournment, and his Lordship directed the petition to stand over for a week.

War Maps .- Messes. W. T. Henley's Telegraph WORKS CO., LTD., of Blomfield Street, London Wall, E.C., have issued a pocket war map booklet illustrating the various war areas in Europe. Copies will be sent to electrical readers on application.

# WAR ITEMS.

U.S. Electrical Exports in January.—The following data on the electrical exports of the United States for January are published by the American "Electrical Review and Western Electrician" from the government report on the foreign commerce of that month issued by the Bureau of Foreign and Domestic Commerce. The total value of electrical shipments in January was the highest since last May, but was nearly 10 per cent. below the total of the corresponding month a year ago. In the four classes for which numbers of articles exported are given, there were shipped in January: electric fans, 1,278; arc lamps, 35; carbon-filament lamps, 51,825; metal-filament lamps, 189,848. In the following table are given the detailed figures for the various classes reported. Corresponding figures are given for last January and for January, 1914:—

An Austrian Company and the War.—The report for 1914 of the Felten & Guilleaume A.G., of Vienna, states that An Austrian Company and the War.—The report for 1914 of the Felten & Guilleaume A.G., of Vienna, states that the working results were unfavourably influenced by the tensequences of the war, although sales considerably declined in the first half of the year owing to the restriction to a minimum of the orders placed both by the government and municipal authorities as well as by industrial undertakings. After the war broke out a complete stoppage, except for orders for army purposes, took place in the cable department, but in the further course of time a demand was again manifested, the Vienna Municipal Council in particular having given large orders. The difficulties in the way of procuring raw materials, and the dearness of these, largely increased the cost of production and diminished the earnings. On the other hand, the iron and steel works in Styria found ample compensation in the great requirements of the Army authorities for the deficiency in the normal class of business. The accounts show gross profits of £106,000, as contrasted with £144,000 in 1913, and net profits of £57,000, as against £92,000. It is proposed to para dividend of 10 per cent. on the ordinary share capital of £354,000, as compared with 15 per cent. in the previous year. The directors state that, although no definite opinion can be formed as to the business prospects for the current year, they believe that after the termination of the war exceptionally large requirements will be experienced for the re-establishment of destroyed values and the replacement of stocks which have been entirely exhausted.

Opportunities for Manufacturers in Russia.—A correspondent of the "Electrical World" states that the opportunity of the "Electrical World" states that the opportunity of the "Electrical World" states that the opportunity of the "Electrical World" states that the opportunity of the "Electrical World" states that the opportunity of the "Electrical World" states that the opportunity of the "Electrical World" states that the opportunity of the "E

which have been entirely exhausted.

Opportunities for Manufacturers in Russia.—A correspondent of the "Electrical World" states that the opportunities for electrical trade are great in Russia, but it is not a simple matter to secure and develop the trade. The most densely populated parts of Russia, starting from the Gulf of Finland, are the cities of Revel, Riga, Windau, Libau, and Mittau. Most of the people are of German and Scandinavian descent, and prefer to talk German rather than Russian. The people living between Mittau and Warsaw are of Lithuanian and Polish descent, and do not like to talk Russian at all, because they hate Russians and the Russian language, so that one must use German if he wishes to transact business with them. Most of the apparatus in service is operated at 110 volts or 220 volts direct current, except the street railways, which are 500-volt systems. A small part of the apparatus is of English make. American goods are considered superior, but the people know very little about them. For American manufacturers wishing to open offices for consulting engineering or sales work in Russia the best location is Riga or Petrograd. The office should be put in charge of a Russian-American who is familiar with Russia and her people and with American advertising. advertising.

Rifle Shooting.—Like most other districts, Merrie Islington has its Civic Guards, and a site for their rifle practice has been offered, free of charge, by Messrs. A. P. Lundberg & Sons, adjacent to their works, which are practically in the centre of the borough.

Board of Trade Assistance.—The Commercial Intelligence Branch of the Board of Trade has issued its weekly list, to April 3rd (No. 15), of inquiries for sources of supply of

Munitions of War.—The following are the terms of a resolution, passed by the undernoted societies on Sunday last, with respect to the production of munitions of war:—"We, representing the trade unions in the shipbuilding and engineering trades of the North-East Coast, welcome most heartily the establishment of a committee on which the working men, the employers, and the Government departments are represented. We do not want any more speeches about the failings of the workers, the employers, or the Government; we want to pull together and get on with it. You may tell Lord Kitchener that we shall deliver the goods. The working man of the North-East Coast will do his bit." The societies concerned are:—Associated Blacksmiths, Boilermakers and Iron and Steel Shipbuilders, United Brass Founders and Finishers, Amalgamated Cabinetmakers, General Union of Carpenters and Joiners, Northern Enginemen's Association, Amalgamated Society of Engineers, Electrical Trades Union, Gas Workers' and General Labourers' Union, National Amalgamated Union of Labour, United Machine Workers, National Amalgamated Union of Painters and Decorators, United Patternmakers, United Operative Plumbers, Ship Construction and Shipwrights' Association, Sheet Iron Workers' and Light Platers' Society, United Kingdom Society of Smiths and Strikers, Amalgamated Society of Woodcutting Machinists, Ironfounders' Association, Steel Smelters, and Amalgamated Society of Carpenters and Joiners.

Municipal Workmen for Armament Factories.—The Munitions of War.—The following are the terms of a

Association, Steel Smelters, and Amaigamated Society of Carpenters and Joiners.

Municipal Workmen for Armament Factories.—The appeal of Lord Kitchener for the Birmingham Corporation to release as many men as possible from its services, in order that they may be employed by the Government in the manufacture of munitions and other war requirements, has a result of which the Lord received full consideration, as a result of which the Lord Mayor of Birmingham has issued a statement in which he shows that, while speedy compliance is not easy, seeing that a large number of the Corporation's employés are already serving with the Colours, it can, by the exercise of care and the re-organisation of duties, spare 1,062 men, taken from the following departments:—Public works, 233; care and the re-organisation of duties, spare 1,062 men, taken from the following departments:—Public works, 233; gas, 200; water, 57; electric supply, 5; lighting, stables and refuse disposal, 165; parks, 48; public health, 20; estates, 9; asylums, 1; tramways, 311; education, 13. Of the large number already serving with the Colours (2,615 out of 15,267, or 17 per cent.) 155 (out of a total of 701, or 22 per cent.) are from the electric supply department, and 895 (out of a total of 3,430, or 26 per cent.) are from the tramways department department.

Germans at Shanghai.—The "Times" correspondent at Shanghai states that British shareholders there are making a determined effort to unseat all German directors of British companies. "The feeling is strong that in order to uphold British prestige the Government should definitely declare trading with enemy subjects in China illegal."

Enemy Goods for Australia.—An Australian paper just to hand states that about the middle of February a large quantity of machinery, addressed to the Sydney Municipal Council, was detained by the Customs authorities on the ground that it was enemy goods. The machinery was taken to Sydney in the "Annam" from Copenhagen.

taken to Sydney in the "Annam" from Copenhagen.

Roll of Honour.—Private Geo. Riley, of the 4th Liverpool Regiment, who has died from wounds received at Neuve Chapelle, was formerly employed by the National Telephone Co., at Stockport. He was 19 years of age.

Intelligence has reached St. Albans of the death at the front of Mr. Frederick Vicary Smith, who was an electrical engineer at the North Metropolitan E.P. Supply Co. at Camp Field, St. Albans. Deceased, who was in his 23rd year, went to France on Christmas Eve with the Herts. Regiment. He was buried in the town cemetery of Bethune. He was buried in the town cemetery of Bethune.

Personal.—Mr. W. E. Miller, one of the representatives of the electrical cooking and heating department, of Carron Company, has been granted a commission in the 16th Battalion Highland Light Infantry. Since the war commenced, about 60 per cent. of the staff of this department have

Book Notices. — The Universal Electrical Directory (J. A. Berly's). 1915. London: H. Alabaster, Gatehouse and Co. Price, complete "B," 21s.; "A" (British and Colonial only), 12s. — The electrical trade has come to regard the Red Book of the electrical industry as one of the most essential parts of its office equipment. Though the work of checking and revision of names and addresses on so large a scale in all parts of the world has been exceptionally difficult owing to the war, the contents have been rendered as complete and accurate as could well be expected. The entries in directories like exerything else contents have been rendered as complete and accurate as could well be expected. The entries in directories, like everything else British, European and Colonial, must inevitably be affected by present international occurrences, seeing that many electrical men in many countries are still young and of military age, and that colossal death-rolls and changes of occupation will yet ensue before hostilities come to an end. These unfortunate circumstances, however, in no way lessen the need for this publication; indeed, it may be said that the Colonial and foreign trade aspects of the position render it more necessary than ever for British of the position render it more necessary than ever, for British electrical manufacturers and traders are particularly anxicus to secure information respecting undertakings in other countries which, under the anti-German and anti-Austrian sentiment of the times, want to secure British machinery and apparatus. The book itself is so well known, now that it has reached its 34th year of publication, that it is needless to detail its contents. It is a directory pure and simple, of electrical and allied men, companies, and systems, and is divided up into suitable sections covering respectively British, Colonial and foreign countries, Continental countries, and the United States. The alphabetical sections in each case are followed by classified trade sections, and, as usual, there is the well-tried British geographical section which travellers and others so highly value. The information regarding systems of supply at home and abroad is another department in which the Red Book has thoroughly established its reputation for usefulness. For the convenience of those who require only the British and Colonial sections these are published separately as Vol. "A."

British Standard Specification for Portland Cement. A new which, under the anti-German and anti-Austrian sentiment of the

British Standard Specification for Portland Cement. A new elition of the British Standard Specification for Portland Cement British (No. 12), one of the most widely adopted of the Reports issued by the Engineering Standards Committee, has just appeared. Increased fineness of grinding of cement has been legislated for, Increased fineness of grinding of cement has been legislated for, and the minimum tensile strength at seven days of both neat cement and cement and sand has been raised. The clauses dealing with the preparation of the briquettes have been amplified, the procedure being described in greater detail than has previously been done. In the case of both neat cement briquettes and cement and sand briquettes, ramming or hammering is expressly prohibited. The growth of tensile strength at 28 days, both for neat cement and for cement and sand, is now given in the form of a formula in place of the fixed percentages which have been specified hitherto. All the plates have been entirely re-drawn, and two new plates have been added to the specification, which can be obtained from the Committee at 28, Victoria Street, S.W., price 5s. net.

The Telephone Review of the New York Telephone Co. has brought out a "Triumph of Science Edition" to commemorate the completion of the Trans-Continental telephone line on January 25th;

completion of the Trans-Continental telephone line on January 25th; the issue is worthy of the great occasion, and contains a number of interesting illustrations and articles bearing upon the work which first enabled the human voice to be conveyed over a distance of 4,500 miles. We extend our congratulations to the company both on the achievement itself and on the memorial which it has published.

Our Trade with Australia.—In the course of an interview printed in a Sydney newspaper, Mr. G. T. Milne, British Trade Commissioner in Australia, after condemning rash generalisations respecting the conservation of the British manufacturer, and showing that United Kingdom trade was in a atronger position than ever before, stated:—"The whole problem of how to get trade is changed from the days when orders to a very large extent filtered through the hands of the London merchant, and it was not necessary for the manufacturer to permerchant, and it was not necessary for the manufacturer to personally engage in the hunt for markets. Nowadays, the latter method must be practised, or the manufacturer will be left at the post. This is the point up to which the English makers must be brought—the systematic and persistent seeking of markets, and I hope to see English firms establish responsible representatives in Australia, so that the most satisfactory amount of trade may be done between this Dominion and the Old Country. Small firms could combine to be jointly represented here. It is in this matter of being thoroughly represented on the apot that the English manufacturer can hurry up with advantage, and, where it is found that the tariff makes it advisable, branch factories could be established in order to cope with the trade that has been secured by nursing the local market and studying its requirements."

Trade Announcements.—Messrs. Chiswell & Co. announce that their offices are at Imperial House, Kingsway, London, W.C., and all communications should be addressed there.

THE HARPER ELECTRIC PIANO (1910) Co., LTD., has changed its title to the Harper Piano Co., Ltd., as, while it will still continue the electrical side of its business, it will do a bigger business than formerly in ordinary pianos.

# LIGHTING and POWER NOTES.

Australia.—The Sydney (N.S.W.) city electrical engineer as submitted a report of the probable expenditure by the electric lighting department for three years ending December, 1917, beyond what has already been approved by the Sydney Municipal Council; this includes for the power house £200,000; new sub-station and showroom, £90,000; mains and alternating-current sub-stations, £300,000; new buildings for stores and testrooms, £25,000; making a total of £615,000—Tenders making a total of £615,000.—Tenders.

Bacup.—MARKET RATES.—The T.C. has adopted a flat rate of 1½ i, per light for electricity supplied to occupiers of shops and stalls in the market on market days, and a further charge of ½d. per light per hour on other nights.

Belfast.—LARGE DIESEL-ELECTRIC PLANT.—What is stated to be the largest Diesel engine so far constructed has recently been installed at the shipbuilding yard of Messrs. Harland and Wolff. The engine, which was built by Messrs. Sulzer, is employed for the generation of electrical energy for lighting and power purposes in the shops; it is of the single-acting two-cycle type, and comprises six cylinders, 29.5 in. bore × 39.4-in. stroke, and has been designed to develop 3,750 H.P. at a speed of 142 R.P.M.

Burton-on-Trent.—RATE RELIEF.—The T.C. is now recommended to appropriate £5,000, instead of £4,000, from the gas and electricity departments in aid of the rates for the ensuing

Canada.—The Ontario Hydro-Electric Commission is now supplying current in bulk to three townships, 102 municipalities, and over 800 rural industrial enterprises. It was anticipated that by March over 100,000 H.P. would be distributed. pated that by March over 100,000 H.P. would be distributed. The Chairman of the Commission recently stated that, apart from the benefit of cheap power to industries, the Province of Ontario would soon have 1,000 miles of publicly-owned electric railroads, and those would pay from the day they started operations. Already, in some districts, electric power was being applied to farm work. Farmers were cutting their ensilage and filling their collections are electrically and were commencing to use electrically. farm work. Farmers were cutting their ensuage and ninng their siles by electricity, and were commencing to use electrically-driven threshing machines. The farmhouses, barns and stables were also lit by electricity, and power was used for domestic purposes, such as washing and ironing.

The Ontario Hydro-Electric Commission proposes to place all

municipal electric plants under the management of local commissions; a Bill to this end is now before the Ontario House. In Ottawa and Toronto, which cities both have municipal electric plants, the Commission will be composed of the Mayor ex-officio, one member appointed by the City Council, and one member by the Hydro-Electric Commission—a Board of three. At present the municipal plant is managed by the four members of the Board of Control and the Mayor.

Carnaryon.—Proposed Loan.—The T.C. has applied for a loan of £500 for contemplated main extensions. The National Electric Construction Co. has written, suggesting that if, as was anticipated, the L.G.B. refused to sanction loans for further extensions, the Council should agree to the works being transferred to it or to a subsidiary company, on terms to be arranged. It was decided on April 6th to reply that the suggested transfer was ultra vires.

Continental Notes.—Norway.—The Odda Electrical Co. was started in 1913, with a capital of £500, to develop a small water-power, and up to the present its working shows a total surplus of no less than £800, or 145 per cent. of the capital. Electrical energy has been supplied for technical uses at such low prices as £3 per H.P.-year. Among the consumers are several farmers, who are using the energy for agricultural purposes, and as soon as the proposed extension of the station is completed, this example will be followed by pretty well all the farmers in the neighbourhood.

The Municipality of Ovre Eker, near Drammen, has under erection a new electrical works, which will derive their power from a waterfall at Hangsund. The station will be completed in the course of the summer, and the energy is partly to be used for

industrial purposes.
- It is reported from Notodden that the building operations at Rjukan II have been making good progress, and it is expected that the electrical station and the nitrate factories will be completed sometime in the course of the autumn.

The nitrate works at Notodden are to be extended, and four

large acid towers provided in addition to those already in use.

The large works for the manufacture of ammonia have been completed, and are now in full use. This product was previously imported, but now the company not only meets its own requirements, but also disposes of a good deal for export.

The new electrical works at Skien have been taken over by the The new electrical works at Skien have been taken over by the municipal authorities; energy is derived from a waterfall, which is located in a distance of 5½ miles from the town. The cost of the new works amounted to £34,000, and there are now subscribers to a total amount of 1,200 H.P., of which 600 H.P. are to be employed for lighting purposes. The revenue from this is estimated at £7,000, and the total expenses at £6,300.

SPAIN.—A concession has been granted for the establishment of a plant to utilise the water-rower of the River Molins near

a plant to utilise the water-power of the River Molins, near Tobera (Province of Burgos), in the generation of electrical energy for lighting and power purposes in the district.

A further concession authorises the use of the waters of the Rio Mundo, in the Province of Albacete, for the production of electric

-B. of T. Journal

HOLLAND.—A Special Commission, which was appointed some three years ago in order to investigate the question of the national supply and use of electric current, has recently completed its report. The consumption of electric current for lighting is expected within the next few years to amount for the whole country to 84,787,000 kw.-hours per annum.

The result of the investigation shows that the larger industry should not pay more than 0.4d, to 0.6d, per kw.-hour (and at this price some of the large stations are already able to supply current), whilst the smaller industries probably would use electric energy even at a price of 1 6d. to 2d. per kw.-hour. The annual consumption to be expected is calculated at 170,858,000 kw.-hours for the larger industries, and 12,151,000 kw.-hours for the smaller

The amount of electrical energy likely to be wanted for agricul-The amount of electrical energy likely to be wanted for agricultural purposes is estimated at 3,690,000 kw.-hours, but a considerably larger amount is calculated for the many pumping stations, locks, &c., peculiar to Holland. These installations require a considerable amount of power, which is at present supplied by wind-mills, steam engines, motors and several electric stations. The former represent an aggregate capacity of 6,700 kw.; the steam engines, &c., of 18,740 kw.; and the likely annual requirement of electric energy is calculated at 13,500,000 kw.-hours. This figure would be more than trebled should electric power also be used for the contemplated laying dry of the Zuyder-Zee, inasmuch as this is expected to demand an annual aggregate of energy of as this is expected to demand an annual aggregate of energy of about 34,000,000 kw.-hours. At present there is electric traction on the Hague-Rotterdam Railway and on eight tramways, but there is a question of electrifying, perhaps, half-a-dozen other lines where steam traction is used at present.

Crewe.—The Electric Lighting Committee has deferred consideration of an application from the Crewe Tradesmen's Association for electricity meter rents to be dispensed with until after the war.

Dartford.--Owing to the increased cost of coal and to the fact that the new plant is not yet in working order, the Electricity Committee anticipates a deficiency of £1,072 in the working of the undertaking during the six months ending working of the ur September 30th next.

Dewsbury.—Public Lighting.—The Electricity and Tramways Committee has approved of the electrical engineer's estimate, amounting to £3,460, for lighting the streets in Ravensthorpe by electricity.

-L.G.B. INQUIRY.—An inquiry was held on Dover.-April 14th into the Corporation's application for a loan of £6,000 for new plant at the electricity works. The electrical engineer states that if the loan is refused other steps can be taken at the

Dunfermline.—The contractors for the new reservoir at Glenderon, Messrs. P. & W. Anderson, Ltd., propose to lay down a complete electrical installation for the driving of all the plant required in the constructional work.

Eton.—On account of reduced lighting, the electricity company has allowed a reduction of £5 9s. from the lighting account of the U.D.C.

East Grinstead.—B. of T. Inquiry.—On April 7th an inquiry was held regarding the application of the U.D.C. for a prov. order for electric supply. It was stated that there was a demand for electricity, and that at the present time there were 29 private electric light plants in the town. A private company was registered 19 or 20 years ago for the purpose of providing electricity, and the gas and water company in 1892 obtained power to apply for an order, but nothing had been done in the matter. It was proposed to run the works in connection with the refuse destructor, and the estimated cost was about £10,000. A hurried canvass taken at the request of the B. of T. showed 103 applications in the compulsory area and 74 outside, with only seven refusals. The estimates showed a loss of £182 on the first year's working and £68 on the second, and a profit of £102 on the third. Only seven persons objected to the scheme, and they resided within 300 yards' radius of the proposed site, which had been approved by the L.G.B. for the destructor.

Hale.—Proposed E.L.—The Aldershot U.D.C. has empowered the chairman of the Lighting Committee, the electrical engineer and the clerk to discuss with the Farnham U.D.C. the question of electric light at Hale. The parish is within the area of supply for electricity of the Farnham Gas Co.; and writing the Aldershot Council on the matter, the chairman of the Farnham U.D.C. says that it appears to his Lighting Committee that it should not be within the gas company's power to sterilise that part of the urban district in regard to the provision of electric supply, and that it may not be impossible to secure the desired supply by other means.

Hendon.—The specifications of work in connection with the installation of electric light, &c., prepared by Mr. H. S. Brackenley, have been adopted by the Guardians.

Holme (Yorks.).—VILLAGE LIGHTING.—An electricity scheme has been promoted locally. It was decided to work it with 800 £1 shares, and the villagers quickly applied for 1,110 shares, and there had to be a process of selection. The company has acquired an old mill with water power, by which it is proposed to generate the current. During the Easter holidays the young men of the village gave their services in making certain desired alterations to the premises. A dynamo is to be purchased. The contract for the wiring has already been let to Messrs. Graham & Co., of Huddersfield. Public and private lighting will be undertaken. For house lighting it is proposed to charge a minimum of 30s. per year for three lights, with an extra charge of 4s. per year for additional lamps.

India.—The electrification of the Bombay Mint will be taken in hand shortly, and Captain Willis, R.E., is returning to Bombay for the purpose.—Indian Engineering.

Irish E.L. Schemes.—A Tipperary journal mentions that electric lighting is steadily coming into more general use in the towns of that extensive county. Fethard was the first to try the system; Roserea is now lighted by an electric plant established at the local bacon factory; Clogheen has replaced oil lamps by electricity for public lighting, and Cahir has taken steps to form a company to supply electricity; Enniscorthy, in County Wrexford, has taken steps, through its Urban Council, to obtain a prov. order to carry out a scheme.

Leigh.—Proposed Loan.—Application for sanction to the borrowing of £2,813 for extension of plant at the electricity works is to be sought by the T.C.

Lincoln.—RATE RELIEF.—The Electricity and Tramways Committee has decided to recommend that out of the current year's profits the sum of £1,500 be applied in the relief of rates for the year ending March 31st, 1916, and that, if necessary, a further sum of £500 be available.

London.—St. Marylebone.—A statement as to the December quarter's working shows that the gross profit was £39,797, as against £45,143 in 1913, the decrease being due to reduction in income amounting to £6,378, while expenditure fell by £1,032. Some 4,614.801 units were sold, as against 5,391,954 in the same period of 1913. Taking the nine months to December, the gross profit was some £3,740 less than for the same period of 1913. As regards the estimates for the year 1915-16, special charges due to the war figure at £12,000, while capital charges are about £800 higher, and taking all into account a net credit balance of £2,626 is expected.

Loughrea, Co. Galway.—Mr. John Murphy, who has been for some years in charge of the electric lighting plant at Clonmel Asylum, has been appointed manager of the new electric lighting works at Loughrea.

Middleton.—MILL SUPPLY. — The T.C. has made arrangements with the Manchester Corporation for a supply of electricity for Neva Mills, and the laying of the cable will cost Middleton about £3,000. The cable will be big enough to bring electricity to the mill and to supply the borough generally if necessary, and the town will thus have a sort of stand-by. The arrangement with the mill is for 20 years, but may be terminated at the option of the mill company at 7, 10 or 15 years.

Newport (Mon.).—PRICE INCREASE.—Owing to the increased cost of coal, materials, and labour, the Electricity Committee of the T.C. has decided to raise the price of current after June by 20 per cent.

Oulton Broad. — RESTRICTED LIGHTING. — The Electricity Co., having been applied to for an abatement off the public lighting account for the quarter just closed, owing to restricted lighting, has offered 10 per cent. The U.D.C. has replied that it is of opinion that it is entitled to a much larger abatement, if not total exemption.

Portstewart.—E.L. Scheme.—A system of electric lighting was introduced last week and has proved a success. The current is produced at Millbank, where a power station has been fitted up.

Queensbury.—The U.D.C., after considering amendments to the Bill of the Yorkshire E.P. Co., has decided to support the Bill.

Runcorn.—The Mersey Power Co., Ltd., announces that in spite of the present abnormal price of coal, its charges for current are not being increased.

Shanklin. — RESTRICTED LIGHTING. — The Isle of Wight E.L. Co., having offered a deduction of £37 10s. from the lighting account for the March quarter on account of restricted lighting, the U.D.C. has asked for a further reduction, as only 47 of the 222 lamps are in use.

Shelf.—The U.D.C. has decided to support the York-shire Electric Power Co.'s application for lighting powers.

St. Annes-on-Sea.—The electrical engineer reports that lately there has been a gratifying increase in the output of current, the demand for heating purposes being especially notable. The consumers number 1,622.

Stafford.—After having received reports from the gas and electrical engineers and considered the matter, a special Committee recommended to the T.C. on Tuesday that—(a) The control of the gas and electricity works continue under one Committee as at present; (b) that no change be made in the management of the gasworks; (c) that Mr. W. H. Robins be appointed engineer and manager of the electricity works, presenting his reports direct to the Committee; (d) that Mr. W. M. Valon be appointed secretary for the electricity works, and countersign all orders exceeding £10 in value.

A proposal was made for placing the two concerns under separate control but was defeated, and the Committee's recommendations carried.

Swansea.—The electrical engineer has forwarded to the L.G.B. a list of employés who could be spared from his department for work on the manufacture of munitions of war.

Sheffield.—The Establishment Committee has approved of the Electric Supply Committee appointing an assistant mains engineer. The Electric Supply Committee has received an application from the military authorities for a supply of current to the South Yorkshire Asylum, Wadsley, outside the area of supply; it is proposed to make application to the B. of T. for sanction to the supply being given.

Torquay.—PROPOSED LOAN.—The L.G.B. has refused to sanction a loan of £1,800 for the purchase of property required for offices and stores in connection with the alterations at the generating station. The Electric Lighting Committee has asked the town clerk to make such financial and other arrangements as may be required to meet the case, and to communicate with the Board expressing the hope that the application would be considered at a future date.

Tunbridge Wells.—Arising out of the recent L.G.B. inquiry into the application of the T.C. to borrow £8,137 for electric lighting purposes, the Lighting Committee has recolved to instruct the engineer to report on the provision of steel headers to two boilers in place of the existing cast-iron headers, and on trunning non-condensing of the plant, &c., during the proposed rebuilding of the existing cooling tower; also to instruct the clerk to complete the contract with Witting & Partners for dismantling the existing cooling tower and building the new tower. The Committee has adjourned consideration of the report on the extension of mains until after the extension order has been granted by the B. of T. Application is to be made to the Board for consent to the supply of energy to Rusthall and Southborough, outside the area of supply.

Turton (Lancs.).—A number of applications have been received for electricity at Edgworth, but the D.C. has deferred consideration of them until after the war in consequence of the dearness of materials and labour.

Walsall.—LOAN SANCTION.—The L.G.B. have sanctioned the borrowing of £16,700 for the purposes of the electricity undertaking, viz., £13,000 for mains, £500 for services, and £2,900 for transformers. In view of the representations made by the Board in favour of reducing capital expenditure, the Committee has decided that any further extensions which are not required by manufacturers for war purposes will, for the present, be only carried out on the applicant providing the cost of the service. The electrical engineer has been given instructions to negotiate for a site in the Bescot district for a sub-station.

Warrington.—The Electricity and Tramways Committee has decided that the rent charged to tradesmen for the hire of outside arc lamps be reduced by one-half owing to the reduced lighting regulations.

Wigan.—Proposed LOAN.—Application is to be made to the L.G.B. for sanction to borrow £6,000, the estimated cost of two boilers for the electricity works.

Willesden .- In the course of his speech as to the year's Willesden.—In the course of his speech as to the year's working, Mr. G. H. Hiscocks, referring to the electricity department, said that the 12 months started well in advance of all previous years, and up to the outbreak of war the purchase of energy from the Power Co. showed an increase of 20 per cent. This state of affairs, however, could not continue in view of the large reduction in public lighting since that date, but much new business had been secured, and the probable result of the year's working will be that the purchase from the Power Co. will be about 5 per cent. higher than in the preceding 12 months, while a number of important developments are being put in hand by various firms which, it is hoped, will substantially and permanently increase the revenue of the department.

# TRAMWAY and RAILWAY NOTES.

Aberdeen.—The Corporation Tramways Committee has instructed the manager to report as to the cost of altering the stairs on the cars recently operated on the P.A.Y.E. system, to the ordinary arrangement,

Bolton.—RESTRICTED SERVICES.—In consequence of enlistments—25 men from the department enlisted during the week-end—the Tramways Committee has this week curtailed the car services on five routes, and further curtailments on other routes will be made as and when necessary.

Canada.—The equipment of the Montreal Tramways Co. at Hochelaga power station has been extended by a 2,000-KW., B.P.M. turbo-alternator set, to be used for peak loads and stand-by, and capable of withstanding 25 per cent. overload for 24 hours, and 50 per cent. overload for two hours. The turbine is by Belliss & Morcom, and its moderate speed is claimed as a special feature. The guaranteed steam consumption is 9'8 lb. per H.P.-hour, using steam at 200 lb. 570° F., and with 28 in. vacuum. The blading is of the impulse type, the disk stage comprising two rows of Curtis steel blades compounded for velocity and the drum stage, phosphor-bronze blading compounded for pressure. A Michell main thrust bearing is used with a ball thrust coming into action only if the main thrust fails. Main and emergency governors act through an oil relay system, and a multi-jet ejector condenser is used. The alternator is a standard Swedish G.E.C. machine with 35-kw., 575-kw. engine-driven exciter.

Edinburgh.—The Tramway Committee is experiencing difficulty in getting a self-propelled car for the purpose of experimenting, and at last week's meeting it was suggested that as an alternative, one of the present cars be converted.

A report by the Tramway Committee as to the cost to the city had Colinton tramways been purchased (as suggested by the Commissioners at the recent provisional order inquiry) shows that for missioners at the recent provisional order inquiry) snows that for the price which the Corporation was asked to pay (£9,000), it would receive nothing of any value to it. The Corporation would have been liable for a sum of probably £12,290. The Tramway Committee has unanimously approved of the action of the Sub-Committee in declining to accept the conditions laid down by the Commissioners.

Manchester.—The Tramways Committee has decided to recommend that steps be taken with a view to an application being made in Parliament in the Session of 1916 for an extension of time for the construction of the Northenden Road (Sale)

At the meeting of the Tramways Committee, on Tuesday, a statement was issued showing that the number of eligible men in the service of the tramways at August 1st, 1914, was 2,895, but since then no less than  $56^{\circ}31$  per cent. have joined the Colours. This number includes 876 married and 753 single men, total 1,629. Two hundred trolley boys have joined the Army. The total liability of the Committee for dependents is £1,113 per week, and since the outbreak of the war £26,924 has been paid.

-A report by the general manager that there Oldham.was not a satisfactory weather-screen device for tramway drivers on the market, was criticised at a meeting of the T.C. on April 7th; it was stated that 70 per cent, of corporations and companies used screens of one sort or another, and that further inquires were being made.

Rochdale.—YEAR'S WORKING.—The gross tramway receipts for the year ended March 31st (excluding Heywood's proportion) amounted to £78,771, or £226 more than in the preceding year. The undertaking is said to be the only one in Lancashire, save Preston, which reports increased takings last

South Shields. - YEAR'S WORKING. - The tramway receipts for the year ended March 31st last totalled £39,627, com pared with £38,260 in the previous year, an increase of £1,376. The miles run were 927,727, an increase of £0,712, and the passengers carried numbered 10,479,421, as compared with 10,005,164, an increase of 474,257.

U.S.A.—ELECTRIC CABS.—Some trials are being made in New York with an electric taxicab in connection with a proposal to start a service of such vehicles at the principal railway termini. The vehicle is covering a distance of 70 miles per day on a single charge of the battery, plus an hour's boost at mid-day.

Walsall.—The tramway manager has been instructed to proceed with the relaying of a portion of the Walsall Wood tramway extension as soon as the work in connection with the new road from Ablewell Street to Birmingham Road has been completed.

YEAR'S WORKING.—The net profit of the Corporation tramways for the past year amounted to £2,479, of which it is proposed to devote £2,000 to the relief of the rates. It was pointed out that the passenger receipts amounted to £34,310, and they had carried free \$1,000 soldiers and 2.000 refugees. In constitution with an application but the amplication by the complexion of the passenger receipts. nection with an application by the employés for increased wages, a proposed Corporation bonus of 2s. to 2s. 6d. per week is not regarded as satisfactory, and something in the nature of a deadlock has arisen.

# TELEGRAPH and TELEPHONE NOTES.

Post Office Tube Flooded.—A sudden inundation of the Post Office tube, which imperilled the lives of a gang of men working on its construction, occurred about midnight on April 8th. The tube, after leaving the Post Office at Mount Pleasant, runs westwards under the centre of Calthorpe Street at a depth of between 40 ft. and 60 ft. Ten men were working in the head westwards under the centre of Calthorpe Street at a depth of between 40 ft. and 60 ft. Ten men were working in the head shield, outting their way through the earth, when the water began to coze through upon them. At first they tried to keep it out with boarding, but the percolating water gradually gained in volume, and at length the men had to run for their lives. The last man had scarcely got to a place of safety when there was a tremendous rush of water. In a very short time the tube was full. Many days must elapse before work on the tube/can be resumed. Shortly after the inundation there was a sudden subsidence of the roadway in Calthorpe Street, leaving a cavity 20 ft. deep.—The

Secret Wireless on Board Ship .- Recently the Dutch wireless stations intercepted a message from Zeebrugge in code, which was found to refer to the movements of shipping, and suspicion was aroused that it was addressed to a large German ship called the Main, which was lying in the harbour at Flushing. On examination it was found that a secret wireless installation in full working order existed on the vessel, the aerial wires being colled round the mast and rigging. The incident was regarded as a grave breach of Dutch neutrality, and orders were given to prevent the further use of the installation.

The Telephone Service.—Hitherto it has been the practice to employ only male operators for night duty in the London telephone service, but it has now been decided to call up women operators for this purpose, owing to the large number of men who have enlisted for war service. They will be called upon, for four nights a week, to take up their duties at 8 p.m. and finish at 8 a.m., in conformity with the official schedule of 48 hours a week.

Three hours out of the 12 are to be given for rest.

The necessity for the innovation is apparent when it is considered that out of the male staff of 1,500 as many as 440 have gone on active service. All these are paid their full salaries, less Army allowances, and guaranteed their positions when they return.

Ten of the staff have been killed in the war, and in accordance with the arrangements made their dependents have received a year's salary .- Daily News.

# CONTRACTS OPEN and CLOSED.

#### OPEN.

Aldershot.—April 20th. U.D.C. One 400-kw. D.C. turbine set, complete with surface condenser and circulating pumps, &c. One water-tube boiler with chain-grate stoker. See "Official Notices" March 26th.

May 4th. Steam and other pipework. Water-softening plant. See "Official Notices" March 26th.

Australia.—Melbourne.—April 19th. 13,560 yards

AUSITAHA.—MELBOURNE.—April 19th. 13,560 yards of lead-covered cable, and 13 tons of bare hard-drawn copper cable, for the City Council. See "Official Notices" March 26th.

April 21st. 1,027,900 arc lamp carbons, for the Melbourne City Council. See "Official Notices" April 9th.

June 2nd. Electric lighting material for oars (Contract 28,187).
Tender box, Railway Offices, Melbourne. Particulars at Contractors' Room, Spencer Street.* Deposit ½ per cent. of amount of tender. tender,

June 2nd. Bogie trucks, wheels and axles for 10 cars of the St. Kilda-Brighton electric street railway (No. 28,621) for the Victorian Railway Commissioners.

Victorian Railway Commissioners.*

June 15th. Four mechanically-fired boilers, for the City Council. Specifications (£1 1s.) from the City Electrical Engineer.

June 15th. City Council. One turbine-driven boiler-feed pump, two fuel economisers, circulating water pumps. City Electrical Engineer. Specifications for each item, 5s.

QUEENSLAND.—June 1st (instead of March 16th). P.M.G. Switchboard for Warwick. See "Official Notices" March 26th.

Sydney.—May 31st. Three electric battery locomotives for Public Abattoirs, Homebush, for the Department of Public Works, Specifications, &c., 5s., from the Accountant, Public Works Department.

The City Council will shortly invite tenders for 2,000 insulators, disconnecting switches and fuses, incandescent lamps, and nitroincandescent lamps.

Specifications for the items marked * can be seen at the B. of T. Commercial Intelligence Branch in London.

Corporation. Diesel Basingstoke. — April 19th. engine generating set, motor-generator, balancer, underground cables. See "Official Notices" April 9th.

Bradford.—April 17th. (A) 100 tramear trucks, (B) 200 motors, 200 controllers, 200 automatic circuit breakers, for the Tramway Department. Specifications (A and B) one guines each, from Tramway Offices, 7, Hall Ings.

Darlington.—April 20th. Corporation. 25-ton overhead traveller and economiser. See "O licial Notices" April 9th.

28th. Corporation. Dundee. — April Centrifugal circulating pumps, and 750 ft. of 42-in. and 30-in. cast-iron pipes. See "Official Notices" April 9th.

'rance.—Electric traversers, D.C. electric railway motors, multiple unit control equipments, cables and wiring for traction, heating and lighting, for the Administration des Chemins de fer de l'Etat à Paris. Particulars can be obtained in the Bureaux du Service Electrique (3rd div.), 72, Rue de Rome, Paris, between 3 and 5 p.m. on Tuesdays and Fridays, up to April 30th.

Glasgow.—April 16th. Corporation. Cables, meters, carbons. See "Official Notices" April 9th.

Hull.—The Corporation Property Committee has decided that three electricilitis be obtained, for the City Treasurer's Department, the dity Accountant's Department, and the Rates Depart-

Italy.—Naples.—April 30th. Tenders are invited for the supply and erection of a transmission line, with metallic posts, from the hydroelectric generating station at Volturno (Campobasso) to the reserving station at Naples. The estimated cost of the work is 1,131,955 lire, and a guarantee of 30,000 lire is required of the successful tenderer. Profile drawings, models of poets, &c., with other particulars, may be obtained from the Consiglio-Generale dell'Azienda per l'Ente, Volturno, and tenders must be submitted by April 30th.

Lincoln.—Tramway uniforms, for the T.C. The Electricity Works, Brayford Side North.

-April 20th. Steel girder tramway rails and fish-plates. Mr. J. M. McElroy, General Manager (£1 1s., returnable).

April 14th. Corporation, Three 1,250 K.V.A. static transformers. See "Official Notices" April 2nd.

Mountain Ash. - April 26th. U.D.C. Sub-station building, E.H.T. underground cables, L.T. overhead lines and public lighting, E.H.T. switchgear, L.T. switchgear and transformers, for Abercynon. See "Official Notices" to-day.

Rhondda.—April 17th. U.D.C. Installation, 83 wiring points, 88 lighting points, at the Council Offices, Pentre. See "Official Notices" April 2nd.

Spain.— The municipal authorities of Valverde de Leganes (Province of Badajoz) have just invited tenders for the concession for the electric lighting of the town during a period of

Wallingford.—April 19th. Telephone installation, infirmary to workhouse, with electric bell, for the B. of G. Mr. G. F. Slade, Wallingford.

#### CLOSED.

Basingstoke.—The B.C. has accepted the tender of the Electrical Apparatus Co., Ltd., for the supply of three and five-amp, meters for a period of 12 months. Australia.—The following tenders have been accepted:-

Australia.—The following tenders have been accepted:

Bydney City Council.—
Vehicle-charging apparatus.—Australian General Electric Co., £1,711.
Centrifugal pumps (motor-driven) for power house.—Falkiner, Ltd., £166.
Travelling cranes for sub-stations Nos. 71 and 72.—Loke Muras, £284.
C.I. valves and mild steel chutes.—William Elder & Co., £110 15s.
Copper-oled steel cable.—Western Cable Co., £274.
Water Board.—
No. 1 pumping station, Ultimo.—Centrifugal pumps and electric motors for Third Avenue low-level pumping station.—Zollner, Ltd. (a), £1,060 (recommended); (b), £595; (c), £941; (d), £778; (c), £941; (d), £778; (e), £934.
Centrifugal pumps and electric motors for Elliott Street low-level pumping station, Balmain.—Zollner, Ltd., (a), £1,014 (recommended); (b), £951; (c), £941; (d), £778 (c) £934.
Comm nuwealth —Postmaster-General's Department.—
Telegraph Office, Deniliquin, £30 accumulators; Pritchests & Gold cells, schedule 277a, item 1.—£203, Wm. Adams & Co. (accepted), 175, Clarence Birecton of telephone line between Boree Creek and Greenvale.—£324, M'Donald Bros.
Erection of telephone trunk line between Cootamundra and Junea.—£8,467, M'Donald Bros.

Erection of telephone trunk line between Cootamundra and Junea.—£8,467, M'Donald Bros.
Queensland.—
7,500 tose in fibre tube, schedule 293, item 6.—£281, Western Electric Co. 2,000 telephones.—James Paton & Co.

The Richmond Council received the following tenders for a refuse destructor and auxiliary plant :-

Horsfall & Co. ... Stirling Destructor Heeman & Froude.. Meldrum ... .. .. .. ... (accepted) 10,217

The consideration of the tenders turned largely on the question whether a British or Australian engine should be required, and eventually it was resolved that the successful tenderer indicated above be asked to install a Kelly & Lewis engine and feed pumps of Australian manufacture instead of the English-made engine specified by them. As notice of motion for resolution was subsequently given, the matter was at the date of our information (February 17th) likely to be re-opened.

Belfast.—Messrs. Venner Time Switches, Ltd., have again secured the contract for time switches for the ensuing 12 months. Messrs. Chamberlain & Hookham, Ltd., have received a contract for meters.

Bolton.—The Corporation has placed a contract for the 12 months' supply of motor starting switches with the Electrical

Apparatus Co., Ltd.
The managers of St. Matthew's School have accepted the tender of Mr. J. Morris for installing electric lighting.

Bradford.—The following tenders have been accepted by the Committees interested :-

John Brown & Co., Ltd.—200 steel tires, £437. H. Summersgill.— Iron castings. Collinson Bros.—Wiring the East Ward Branch Library, £126. Smith & Croft.—Cable extensions, at Tachnical College, £30.

-The T.C. has accepted the tender of Mr. Canterbury.-S. Terry, of Canterbury, for an electric motor and fittings for the sludge-mixing apparatus at the irrigation works, at £58.

Clacton-on-Sea.—The U.D.C. has accepted the tender of Messrs. Fitch for an outlet for the Diesel engine cooler, at £13 4e.

Croydon.—Messrs. Siemens Bros. Dynamo Works, Ltd., have secured the contract for the annual supply of Wotan, Tantalum, and carbon-filament lamps to the Corporation tramways.

Dartford.—The U.D.C. has accepted the tender of Messrs. J. Waddell & Sons for 350 tons of Kirkby rough slack for the electricity works, at £1 1s. per ton, and 150 tons of South Leicester nuts, at £1 2s. per ton.

Dewsbury.—The Electricity and Tramways Committee has accepted the tender of the Mackintosh Cable Co., at £164, for a mile of cable.

Glasgow. — The Tramways Committee recommends acceptance of the following offers:-

Switchboard, Govan Depôt.—Ferguson, Pailin & Co. Roller shutters, Langside Shelter.—A. L. Gibson & Co. Adhesive tape.—L. Andrew & Co. Trolley wire.—J. Halley Craig.

Hove.—The electrical engineer has reported upon the the tenders received for the supply of a turbo-generator and a set of battery accumulators. He finds that the best suited for the Council's requirements are a turbine connected with two generators in tandem. For this type of machine five tenders were received. When instructions were given to obtain tenders, it was contemplated that delivery could be obtained so that the new plant could be working in time for the next winter's load, but the engineer's opinion is that, owing to the war, the plant could not possibly be got to work before the middle of next December. The engineer points out that the prices are higher by 20 per not possibly be got to work before the middle of next December. The engineer points out that the prices are higher by 20 per cent. than they were three months ago, but that, in his opinion, the advantage to be gained in economy in working, and the savings to be effected in coal costs, outweigh the disadvantages of the increased first cost of the plant, and that had it not been for the Government's request to defer expenditure at the present time, he would have unhesitatingly advised the acceptance of a tender.

The Lighting Committee, reporting upon the engineer's remarks, states that it has resolved to postpone the installation of the additional turbo-generator plant, and to inform the tenderers states that it has resolved to postpone the instantant of the tenderers accordingly. Nine tenders were received for the battery of accumulators, and the engineer recommends the acceptance of the Tudor Accumulator Co.'s tender, at £701, in respect of which the company also offers to maintain the same for a period of 10 years at a charge of £47 per annum. In conjunction with this battery, the Committee reports that it will also be necessary to have the two sets of battery boosters referred to in the engineer's report of December last. The engineer suggests that separate prices for the dynamos and motors and switchest that separate prices for the dynamos and motors and switchest that separate prices for the dynamos and motors and switchest that separate prices for the dynamos and motors and switchest the set of the order being given. The engineer strongly advises that the new battery to be ready for work in 12 weeks after the date of the order being given. The engineer strongly advises that the new battery should be got to work as soon as possible, as it would enable the Council to give a better distribution of electrical pressure and also effect a good economy in working. The Committee has therefore come to the conclusion that, notwithstanding the recommendations of the Government to that, notwithstanding the recommendations of the Government to curtail expenditure, the installation of the battery is of sufficient importance to warrant the expenditure, and has resolved to recommend to the Council to accept the tender of the Tudor Accumulator Co. and its offer to maintain the batteries. The Council is also recommended to authorise the Committee to obtain and install the two sets of boosters, &c.

Hull.—At a meeting of the Corporation Telephone Committee, it was decided that either of the two lowest tenders should be accepted for the supply of cables, viz.:—

W. T. Henley's Telegraph Works Co., Ltd. -2575. Union Cable Co., Lti. -2547.

London.-BETHNAL GREEN.-The Electricity Committee has accepted the tender of Messrs. Mell was & Co., Ltd., at £52, for patent roof glazing with wired glass at the new substations

HAMMERSMITH—The Electricity Committee recommends the B C. to accept the tender of the Electrical Apparatus Co., Ltd., for BU. to accept the tender of the Electrical Apparatus Co., Ltd., for the supply of ordinary meters for a period of three years, on the understanding that the price of brass rod in March, 1916, is not above 9 l. per lb. Should this price increase the company's price to the Council would be advanced 5 per cent. Also tenders for insulating box filling compound, Limmer Asphalte Paving Co., and for the purchase of scrap metal at the electricity works, Messrs. W & H. Cooper.

Manchester.—Among the tenders accepted for general stores required in the Tramways Department for the ensuing 12 months are the following :-

months are the following:—

Connolly Bros.—Cable (power and lighting), bell wire.

F. Smith & Co., Ltd.—Copper cable (wire and strip).

Till & Whitehead, Ltd.—She et copper and brass wire rod and strip.

F. Smith & Co., Ltd.—Copper cable (wire and strip).

Richard Johnson & Nephew, Ltd.—Galvanised-steel cable, &c.

John Ash on & Sons, Ltd.—Leather belting, &c.

D. Moseley & Sons. Ltd.—Calvanised-steel cable, &c.

British Thomson-Houston Co., Ltd.—Motor and controller parts (B.T.H. equipment), motor cases (B.T.H. equipment), brush holders and spare parts (B.T.H. equipment), half-wat incandescent lamps (sungsten drawn-wire filaments).

D. C. Bate.—Circuit-breaker handles (B.T.H. equipment), pre-sed asbestos division plates (B.W. equipm nt) (portion), fibre dust rings.

Dick, Kerr & Co., Ltd.—Motor and controller parts (D.K. equipment), motor cases (D.K. equipment), armature and field colls (D.K. equipment), controller fingers (D.K. equipment).

British Westinghouse Electric & Mfg. Co., Ltd.—Motor and controller parts (B.W. equipment), armature and field colls (B.W. equipment), spare parts for brush holders (B.W. equipment), traction lightning arresters.

B. Gratrix, inn. & Bros., Lt*,—Hinge pins, are lamp globes, &c.

arresters.

S. Gratrix, jun., & Bros., Lt'.—Hinge pins, are lamp globes, &c.

L. Andrew & Co.—Fullerboard and mica tubus, fibre, &c., insulation tape,
Chatterton compound, &c.

Electro-Mechanical B. ake Co., Ltd.—Resistances (grid type) and spare

Electro-Mechanical B. are Co., Lud.—Assessmences (and type) parts.

H. Wallwork & Co., Ltd.—Grids for resistances.

P. R. Jackson & Co., Ltd.—Assembled commutator segments (B.T.H., D.K. and B.W. equipments), armature and fi-ld coits (B.T.H. equipment).

Kay & Co.—Brush holders and spare parts (D.K. and B.W. equipments). Electrical Supplies Co., Ltd.—Controller fingers (B.T.H. and B.W. equipments) (portion).

Dyer & Young.—Controller fingers (B.T.H. and B.W. equipments) (portion).

Equipment & Engineering Co., Ltd.—Trolley poles, trolley heads, &c.

Drake & Gorham, Ltd.—Incandescent lamps, traction type (drawn-wire filament).

Deake & Gorham, Ltd.—Incandescent lamps, traction type (drawn-wire filament).

General Electric Co., Ltd.—Incandescent lamps (carbon filaments and 200 voit drawn-wire filaments), switches, bells, lighting material, telephones, &c.

Ftella Conduit Co.—Steel conduit tubing, &c.

G. Schultz & Co.—Mica segments for commutator bars, &c.

A. Bates & Co., Ltd.—Asbestos.

Pinchin, Johnson & Co.—Insulation varnish and insulating compound.

Morgan Crucible Co., Ltd.—Carbon brushes for traction motors, crucibles, fi-clay material, &c., for titting furnaces.

Alfred Wiseman, Ltd.—Overhead equipment insulating material.

Estier Bros.—Canopy trolley bases, &c.

Fleming, Birkby & Goodall, Ltd.—Trolley-wheel bushes and spindles.

M. Cummins.—Auto-sanding devices.

Hadfields, Ltd.—Steel tie-bars.

Ibbotson Bros & Co., Ltd.—Steel fish bolts and nuts.

W. J. Ritchie & Co., Ltd.—Ball-races for trolley standards.

West Bromwich Spring Co., Ltd.—Truck springs.

Lammell, Laird & Co., Ltd.—Car axles, car-wheel tires (portion).

J. Brown & Co., Ltd.—Car-wheel tires (portion).

F. W. Rowlands & Co., Car.—wheel tires (portion).

British Hele-Shaw Patent Clutch Co., Ltd.—Gear and pinion wheels (portion).

J. Marsden & Co.. Ltd.—Ordinary grey iron castings, chilled iron brake-

(portion). Co., Ltd.—Ordinary grey iron castings, chilled iron brake-block castings (portion)
National Rail and Tramway Appliances Co., Ltd.—Chilled iron brake-block

National Rail and Tramway Appliances Co., Ltd..—Chiled fron brake-block costings.

J. A. Panton & Co. (representing Interchangeable Brake Block Co., Ltd.).
—Chilled fron brake-block castings.

Armstrong Oller Co., Ltd.—Lubricant pads for axle boxes,
J. Carr & Boxes, Ltd.—Trolley cort.

Chamberlain & Hockham, Ltd.—Tramoar type ampere-hour meters,
Thermit, Ltd.—Welding portions.

Maidenhead. — The T.C. has received the following tenders for fuel oil for the electricity works:

 British Petroleum Co., Ltd.
 ...
 £4 13 0

 Anglo-American Oil Co., Ltd.
 ...
 3 17 5

 Anglo-Mexican Petroleum Products Co.
 8 8 0

The electrical engineer has been instructed to make tests with the oil of the Anglo-Mexican Co., and if these are considered satisfactory, arrangements will be made with them for a supply. The last three contracts for fuel oil were placed at £2 3s., £2 7s., and £3 8s. per ton respectively.

Meter Contracts.—Messrs. Chamberlain & Hookham, Ltd., have received the contract from Holyhead for the supply of meters for 12 months. Their tenders for meters for 12 months to Walthamstow and Mansfield have also been accepted.

Rotherham.—The Electric Light and Tramways Committee has accepted the tender of the British Niclausse Co., for two water-tube boilers, at £8,400.

Salford.—The tender of the Pendleton Ironworks Co., Pendleton, for the erection of the steelwork in connection with the central car depôt extension (£1,480) has been accepted.

Sheffield.—The City Council is recommended to accept the tenders of the General Electric Co., at £84, for spares required for the electric light and power plant at the Ewden Valley Waterworks, and for cables, lamps and fittings. The tender of Messrs. A. Reyrolle & Co., Ltd., is also recommended for acceptance, at £236, for one three-phase E.H.T. oil switch and four sets of metering gear.

Sunderland. — The T.C. has accepted the following tenders on behalf of the Electricity and Lighting Committee :—

B.I. and Helsby Cables, Ltd.—Cable, bifurcating boxes.

Ferranti, Ltd.—E.H.T. switchgear cabinet; two E.H.T. switch panels, I.-R., G.-P. and Telegraph Works Co.—Cable.

Banders, Rehders & Co.—C.O. two recorders.

General Electric Co., Ltd.—Metal-filament lamps.

Brunner, Mond & Co.—Supply of alka i.

General Electric Co., Ltd.—D.c. switchboard.

Tunbridge Wells,—The Lighting Committee of the T.C. has accepted the contract of the British Thomson-Houston Co., Ltd., for a 300-kw. steam alternator and condensing plant, at £3,132 instead of at £3,181, authorised on May 18th last

Wimbledon.—The following tenders have been accepted for annual supplies to the Electricity Department :-

ENGINE ROOM STORES.

Pryke & Palmer.—General stores (255 items).

S. Peace & Sons, Ltd.—Files (34 items), chisel and tool steel, and shafting (four items).

James Harvey. —Destructor tools (five items).

CABLES AND CONDUITS.

Western Electric Co., Ltd.—Cables. C. Macint sh & Co., Ltd.—Cable. B.I. & Helsby Cables, Ltd.—Flexible cables.

JOINT BOXES AND JOINTING MATERIAL.

Dussek Bitumen Co.—Compounds (two items).

W. Lucy & Co., Ltd.—Service and other boxes.

Sykes & Sugden, Ltd.—House fuse-boxes.

Callender's Cable & Construction Co.—Frames and covers (three items).

British Electric Transformer Co., Ltd.—Transformers.

Ferranti, Ltd.—Meters.

A. Duckham & Co., Ltd.—Oils.

Wolverhampton.—The Electricity Committee recommends the City Council to accept the tender of Mesers. Mossay and Co., at £630, far a 2½-ton Orwell electric vehicle and equipment.

# FORTHCOMING EVENTS.

Institution of Mechanical Engineers.—Friday, April 18th. At 8 p.m. At Borry's Gate, B.W. Ordinary General Meeting.
Friday, April 28rd. At 8 p.m. At Storry's Gate, S.W. General Meeting, Institution of Electrical Engineers (Newcastle Local Section).—Monday, April 19th. At 7.30 p.m. At the Mining Institut, Lecture on "Illumination," by Mr. V. H. Mackinney.

April 19th At 7.30 p.m. At the Mining Institut, Lecture on "Illumination," by Mr. V. H. Mackinney.

Institution of Post Office Electrical Engineers.—Monday, April 19th, At 5 p.m. At Institution of Electrical Engineers, Victoria Embankment, W.C. Annual General Meeting.

Electrical Trades Benevolent Institution.—Monday, April 19th. At 6.30 p.m. At the Institution of Electrical Engineers, Victoria Embankment, W.C. Annual general meeting.

Rontges Society.—Tuesday, April 20th. At 8.15 p.m. At Institution of Electrical Engineers, Victoria Embankment, W.C. Papers on "Late Radium and X-Ray Burns," by Dr. N. S. Finzl, and "A New Alpha Ray Effect, by Mr. F. H. Glew.

Wireless Society of London.—Tuesday, April 20th. At 8 p.m. At Institution of Electrical Engineers, Victoria Embankment, W.C. Lecture on "Methods of Measurement of the Strength of Wireless Signals," by Dr. E. W. Marchant.

Association of Mining Electrical Engineers (West of Scotland Branch).—Wednesday, April 21st. At 6.30 p.m. At Royal Technical College, Glassgow. Paper on "Bearings of Electrical Machinery," by Mr. A. Baxeter. Discussion on paper on "Some Experiences in the Handling of Electricity," by Mr. M. A. Smellie.

Chemical Society.—Thursday, April 22nd. At 8.30 p.m. At Burlington House, Piccadi ly, W. Paper on "Electromotive Force: in alcohol. Pars VI. Absolute Potentials by the Capillary Electrometer," by Mr. E. Newbery.

Junior Institution of Engineers.—Friday, April 23rd. At 8 p.m. Navy." by Victoria Streat, S.W. Paper on "The Developments of the Navy." by Victoria Streat, S.W. Paper on "The Developments of the Navy." by

Junior Institution of Engineers.—Friday, April 28rd. At 8 p.m. At 89, Victoria Street, S.W. Paper on "The Developments of the Navy," by Victoria Street,

Mr. E. W. Hobbs.

Physical Society of London.—Friday, April 23rd. At 5 p.m. At the Imperial College of Science, South Kensington. Paper on "The Self-Induction of Solenoids of Appreciable Winding Depth," by Mr. S. Butterworth.

National Association of Colliery Managers and Association of Mining Electrical Engineers.—Saturday, April 24th. At University College, Nottingham. Joint meeting. Paper on "Protective Devices against Lightning and Surges," by Messrs, E. Kilburn Scott and L. F. Fogarty,

#### NOTES.

Smoke Nuisance.—At the Manchester Police Court on April 7th, Mesers. Connolly Bros., Ltd., electrical cable manufacturers, Blackley, were summoned for permitting black smoke to issue from one of their chimneys for 6½ minutes on February 27th. The offence was admitted, but in extenuation of the offence Mr. Connolly (one of the directors) pointed out that the firm were completely in the hands of the collieries with regard to coal supplies, and it was utterly impossible at present to secure the right kind of coal for the boilers. They were also handicapped by the scarcity of firemen, and could not get good men even at high wages. He also pointed out that the firm had spent over £600 during the last few months in installing electrical apparatus to combat the black smoke nuisance, and were even now engaged in fitting up additional electric driving plant to take the place of steam. He protested against the action of the Corporation in summoning them at a time when every firm was doing its utmost to keep up Government supplies for all kinds of material. The Stipendiary said the firm were old offenders, and must pay 30s. on this occasion. They had been frequently let off on promising to make alterations which would effectually deal with the black smoke nuisance, but at present that happy state of affairs seemed a long way off.

An Electrical Bridge Over the Blue Nile.—In the course of an interesting article in the Engineer for March 19th on the development of the Soudan, reference is made to the new rolling lift bridge across the Blue Nile at Khartoum, which provides direct railway communication with Khartoum, and has made possible the extension southward of the Soudan Government Railway system. This bridge, which has a length between abutments of 1,834 ft., ranks as the longest and most important bridge in Tropical Africa. In addition to two approach spans, there are seven more spans, each of 218 ft. 6 in., and a rolling-lift span giving a clear opening of 100 ft. The rolling span is electrically-operated and fully locked and signalled. The lighting of the bridge is effected by 36 70-volt Osram drawn-wire lamps, run two in series off the three-phase mains. Current is taken from the Khartoum town supply, and is delivered at the signal cabin at 3,000 volts three-phase, where it is transformed down to 140 volts. Electricity was used as far as possible for all power and lighting during the construction.

Russian Copper Production in 1914.—The production of metallic copper in Russia in 1914 amounted to 1,949,720 poods, against 2,095,288 poods in 1913. The difference, 145,568 poods is about 7 per cent. against 1914. The following table shows the production per district, the largest diminution being shown in the Caucasus, due, no doubt, to the military operations there:—

				1913.		1914.	
Ural	•••	•••	•••	1,055,122	poods	1,025,C55	poods

Chemical works and refineries			84,232	"	86,398	11	
				2,095,288	••	1,949,720	

Power from Sawdust.—Some time ago we mentioned an installation in Sweden of considerable size, in which electrical energy was generated from sawdust; by the courtesy of Mr. F. von Echermany, general manager of the Ljusne-Woxna Co., Ltd., of Ljusne, where the plant is installed, our Norwegian correspondent has been enabled to provide us with the following additional particulars.

The plant is designed for a maximum output of 4,200 H.P., but the first instalment provides for only 2,200 H.P. The fuel consists of a mixture of 80-90 per cent. sawdust and 20-10 per cent. chips, which, as taken from the mill, contains about 50 per cent. water; the mixture will be charged into gas-producers, and provision; is made for the recovery of the tar, wood naphtha and acetic acid from the gas. As the result of tests of long duration, it has been found that the consumption of fuel is 1'8 kg. per H.P.-hour; the fuel costs 1s. per ton at the mill, and contains 50 per cent. water.

It is estimated that the cost of production with a plant of 2,200 H.P., including capital charges, and depreciation at the rate of 10 per cent. per annum, will be 0'42 ore per kw.-hour (0'055d.). Water-power in Sweden cannot be obtained for less than 1 ore per kw.-hour, and this only in a very few cases, the average cost of electrical energy generated from water-power being 2 ore per kw.-hour (0'26d.). It is expected that with wood-waste plant of 4,200 H.P. the cost per unit will be reduced to less than 0 046d.

The installation is being built by the Gasmotoren-Fabrik Deutz,

The installation is being built by the Gasmotoren-Fabrik Deutz, of Cöln-Deutz, which, by means of a special experimental plant erected at Cöln, has solved the technical difficulties met with in the utilisation of wood-waste. The order for the plant was placed in December last, and the first of the two large gas engines was tested at Cöln in February; the whole plant is due for delivery, and it is expected that it will be running in July.

It is calculated that the amount of rower arrighted from wood

and it is expected that it will be running in July.

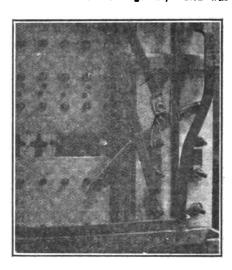

It is calculated that the amount of power available from woodwaste in Sweden, after providing for the driving of the saw-mills, is from 70,000 to 100,000 H.P., varying with the output of sawn timber. The Ljusne-Woxna Co. owns waterfalls near the works of 40,000 H.P., but has found it more economical to make use of the sawdust in the first place than to develop the water-power.

Inquiries.—Makers of cases for pocket electric lamps are inquired for by a Continental firm.

Appointments Vacant.—Junior assistant electrical engineers, over 19 (15s.), for Newcastle-on-Tyne Electric Supply Co.; draughtsman and general technical assistant (£120), for Newport Electricity and Trauways Department; switchboard attendant (30s.) for Torquay Electricity Department. Particulars are given in our advertisement pages.

A Too-enterprising Rat.—The accompanying illustration, for which we are indebted to Mr. C. A. Baker, electrical engineer to the London County Council, shows how an unfortunate rat met with an untimely end.

The view shows the back of a sub-distribution board which controls a portion of the lighting of the Rotherhithe Tunnel. At a recent periodical test it was found that the I.R. both to earth and between poles of one of the paper-insulated cables feeding this sub-board had fallen from 100 megohms, which was the usual

resistance obtaining, to between '5 and 1'0 megohm. There was no apparent cause for the fall, but after examination it was traced to the back of the sub-board, which was then disconnected and taken out of the cast-iron case in which it was mounted; the illustration shows that the rat when climbing up one of the bare copper strip connections got its back in contact with the opposite pole, between which there is a difference of pressure of 100 volts A.C., and was electrocuted.

Municipal Stores: The Need for Organised Buying.

—The Southport Corporation recently formed a special Stores Committee to organise and control the purchasing of stores common to the various departments. The Committee is composed of the chairmen of various other committees—including the Electricity and Tramways Committees—and it is expected that a great saving will be effected by combined buying. A list showing the varying prices paid for similar articles purchased by different committees gives the following interesting comparisons (among others):—For hacksaw blades, the electricity department pays 34s. 9d. per gross for 12 in. × \( \xi_1 \) in. blades, and the tramway department pays 30s. per gross; the prices for block tin range from 1s. to 2s. 6d. per lb.; the Highways Committee pays 27s. 6d. and the electricity department 37s. 4d. per cwt. for white lead; for putty the same committees pay 7s. and 9s. 4d. respectively; boiled linseed oil costs 2s. 2d. per gallon to the Highways Committee, and 2s. 6d. per gallon to the Tramways; petrol prices range from 1s. 2d. (less rebate) paid by the Tramways Committee to 1s. 8d. paid by the Highways Committee; scrubbing brushes cost 1s. per dozen to one Committee, and range down to 7s. per dozen, the Electricity Committee paying 8s.; for soft sosp, the prices range from 35s. per cwt. in the case of the Watch Committee to 1s., the Tramways Committee paying 15s. 9d., and the Electricity Committee 1s. 2d. per cwt. Schedules of goods common to the various departments are to be issued to contractors, and tenders invited for complete supplies.

The Batti-Wallahs.—The Batti-Wallahs' Journal for

The Batti-Wallahs.—The Batti-Wallahs' Journal for January-March contains portraits of the executive, chief of whom is the new president, Mr. Haydn' T. Harrison, and reports of concerts, the annual dinner, and the annual general meeting. The report of the hon. secretary, Mr. F. Pooley, showed that the membership numbered 261.

membership numbered 261.

On March 31st an informal evening was held under the chairmanship of Mr. Wm. Wyld, and was exceptionally well attended; an excellent entertainment was provided.

Patents and Alien Enemies.—Licences have been granted to Messrs, Pintsoh's Patent Lighting Co., Ltd., in respect of patents Nos. 7,049/07 granted to Imray, and 14,950/10, 26.192/10, 19,369/11, 19,370/11, 3,561/13, 8,585/13, and 8,586/13 granted to Julius Pintsch Akt.-Ges.

The I.E.E. Benevolent Fund.—With reference to the appeal on behalf of this Fund, which was published in our last issue, Mr. P. F. Rowell, Hon. Sec. of the Fund, asks us to state that the annual contribution of even the smallest amounts would be greatly appreciated by the Committee of Management.

Russian Architects and Electricity.—At a meeting of the Society of Architects held on March 15th, says a Petrograd paper, M. N. Ph. Savelieff delivered an address on the proceedings of the recent Congress of the Technical Society, which treated of the economic situation of Russis. Deploring, like other Russian authorities, the predominance of Germany in the Russian industrial and mercantile field, he states that French and English products have not much vogue in Russia; and the only branches of the electrical industry that may be said to be in a satisfactory condition in the country include the production of cables and wire, and some electrical machines. Hitherto such have been imported only in small quantities. But the position is a bad one for fittings, such as the control of the production of the leaders and wire and a some second one for fittings, such as the control of the leaders and the leaders and the leaders and the leaders and the leaders and the leaders and the leaders and the leaders and the leaders and the leaders and the leaders and the leaders and the leaders and the leaders and the leaders and the leaders and the leaders and the leaders and the leaders and the leaders and the leaders and the leaders are the leaders and the leaders are the leaders and the leaders are the leaders and the leaders are the leaders and the leaders are the leaders and the leaders are the leaders and the leaders are the leaders and the leaders are the leaders and the leaders are the leaders and the leaders are the leaders and the leaders are the leaders and the leaders are the leaders are the leaders are the leaders are the leaders are the leaders are the leaders are the leaders are the leaders are the leaders are the leaders are the leaders are the leaders are the leaders are the leaders are the leaders are the leaders are the leaders are the leaders are the leaders are the leaders are the leaders are the leaders are the leaders are the leaders are the leaders are the leaders are the leaders are the leaders are the leaders are the leaders are the leaders are the leaders are the leaders are the leaders are the leaders are the leaders are the leaders are the leaders are the leaders are the leaders are the leaders are the leaders are the leaders are the leaders are the leaders are the leaders are the leaders are the leaders are the leaders are the leaders are the leaders are the leaders are th country include the production of cables and wire, and some electrical machines. Hitherto such have been imported only in small quantities. But the position is a bad one for fittings, such as the accessories that are required for the installation of telephone and telegraph wires and electric light. An examination on the premises of the Technical Society of samples of fittings of German production showed that these do not give full satisfaction in respect of quality. Their extensive use in Russia is explained by the low prices charged for them. A special Committee of the Society has prepared an album of the most practical electrical fittings. Most of these are of English production. It is much to be desired, he continues, that the makers of fittings now becoming established in Russia should follow closely the models recommended by the Committee referred to.

A great problem for Russian electricity at the moment is fuel. In most Russian central electric stations coal-fuelled steam engines are in use. Till recently all the Northern area of Russia used English coal. Now recourse has to be had to Donetz (South Russian) coal, some of the varieties of which resemble the English mineral. But putting aside the transport difficulties, there is the fact that the Donetz coalmasters are not equipped for supplying coal to the Northern area; nor are they disposed to accommodate themselves to this new demand from a market that may revert to the English when the war is over. Some of the audience recommended the use of peat, which is so abundant in Russia. But it appears that at the moment Russia is badly equipped for the preparation of peat.

Professional Charges of Civil Engineers.-The Council of the Institution of Civil Engineers has issued a statement to the members with regard to professional charges, with a view to uniformity in the basis upon which such fees are fixed. Engineers with larger experience command fees on a higher scale than younger and less experienced engineers, but the customary remuneration for ordinary professional engineering services, as distinct from remuneration by salary, for the design and superintendence of the construction of works in the United Kingdom is a commission of 5 per cent. upon their cost, which commission, how-ever, is liable to be varied in accordance with the nature and magnitude of works and the character of the services rendered.

nitude of works and the character of the services rendered.

The preparation of bills of quantities, payments to resident engineers and inspectors, and also personal travelling expenses, are matters for arrangement depending upon the nature of the work and the circumstances under which it is carried out. Where the works are designed in sufficient detail to enable a contract for their execution to be made or to enable the Local Government Board to hold an inquiry into the propriety of allowing an authority to borrow money for the purposes of the works, but where the carrying out of such works is deferred indefinitely or abandoned the fee for services up to this stage is one half of the abandoned, the fee for services up to this stage is one-half of the

ordinary commission.

The Council is advised that plans and specifications prepared by an engineer belong, as chattels, to the client, after payment of the agreed fees, but the *copyright* in all original matter contained in such plans and specifications remains vested in the engineer. Neither the client nor any other person is entitled to multiply copies of plans and specifications so far as the original matter therein contained is concerned; and, further, if such original matter has "an artistic character or design," the plans can only be used for the purpose of the particular structure for which they were prepared by the engineer, or for such other purpose as he may

The Concentric Wiring Question in the U.S.A.— At New York, on March 23rd, was held the first meeting of a Committee elected by the manufacturers of electrical supplies and materials entering into electrical construction, under the following

"Besolved, that a representative Committee of business and technical experts be appointed to investigate the all-insulated system of building wiring as used at present in this country, and coincidently investigate grounded return systems together with concentric wiring.

"First—To determine the relative efficiencies of the two systems

(a) as to safety of persons, (b) as to protection against fire, (c) as to the possible provision of methods of wiring at low cost, combined with case of installation and sufficiently attractive appear-

ance to obtain popular approval.

"Second—To present to the entire industry the results of its investigations in the form of concrete recommendations, including

standard systems, standard devices and standard appliances."

In view of the widespread effect of so radical a change in American wiring systems as would result from the complete adoption of grounded returns, the Committee decided to begin its investigations at once by thoroughly sifting the theoretical advantages of that system, and in so far as possible obtaining authentic data of the results obtained in England and Continental Europe, where grounded returns have been used more or less.

Those interested in this subject are invited to address communications to the Committee, care of Mr. Le Roy Clark, chairman, 114, Liberty Street, New York.—Electrical World.

Molybdenum from Australia. — The Times correspondent at Sydney cables that works for treating molybdenite ores have been established in Sydney, and it is expected that over 100 tons will be dispatched to England before the end of Jane from New South Wales and Queensland.

Electromagnets in War Surgery.—It seems likely (writes a correspondent) that when the story of war surgery comes to be written, the electromagnet will be found to have played no inconsiderable  $r\delta le$ . Hitherto in civil practice magnets have been used for extracting foreign bodies only from the eyeball, but the present war, at least so far as French surgery is concerned, has a surgery led their wider near Alexander two companying those have been revealed their wider uses. Already two communications have been made on this subject to the Académie des Sciences of Paris, in both cases by French medical men actually engaged in the field, and the results appear to have been strikingly successful. Not all the projectiles employed in the war, of course, are of a magnetisable nature, and the French copper-sheathed bullets and the French and German lead shrapnel bullets have to be dismissed from the reckoning. It is otherwise, however, with splinters of cast shell, and also with the German bullets which are coated with an and also with the German bullets which are coated with an envelope of ferro-nickel. One of the French doctors, M. Rollet, states that he employs a giant electromagnet capable of supporting a weight of at least 1,150 kilograms (more than 22 cwt.), and taking 23 amperes at 110 volts. It attracts immediately the German bullet, weighing 10 grammes, at a distance of 11 centimetres, and splinters of shell at a still greater distance. This electromagnet is placed over the part where the bullet, as demonstrated by X-rays, is known to be lodged, and it causes a movement of the projectile. This worker states that, owing to the resistance of the tissues, it is This worker states that, owing to the resistance of the tissues, it is not very useful to employ a small hand magnet, but that these very powerful electromagnets often succeed in bringing the bullet or other projectile nearer to the surface or into a more favourable position, and then an extraction with only a small incision becomes

In a later communication to the Académie, Prof. J. Bergonić, of Bordeaux, states that he has also used an electromagnet with success in many cases. The instrument he employs weighs 40 kilograms (88 lb.), and has a magnetic core of special steel 60 mm. in diameter. The magnetising coil takes 3.5 amperes at 110 volts. This has been employed successfully where ordinary surgical pro-This has been employed successfully where ordinary surgical procedure was dangerous. The purely surgical details would scarcely interest the readers of an electrical journal. Suffice it to say, that the electromagnet is kept over the part for 15 minutes or so every day, until after a number of such daily applications, in one case as many as 24, the projectile is brought so near the skin as to cause a cone-shaped raising of the surface at each application of the magnet. When this has happened, extraction by means of the knife is an easy matter. An important point while using the electromagnet is to keep opening and closing the magnetising circuit during the whole of the sitting, and the influence on the foreign body, granted, of course, that it has a magnetisable nature, becomes noticeable on X-ray examination, and ultimately by the sensations of the patient and the raising of the skin.

A Canadian Electric Bakery.—A prominent bakery in Toronto recently installed a Hughes electric oven, which is proving more economical than the furnace type oven which it replaced. Thus, the electric oven with a capacity of 180 1'5-1b. loaves, turned out 15 batches or 2,700 loaves in the property of 180 1'5 lb. loaves to the backet over with a capacity of 180 1'5 lb. loaves to the property of 180 1'5 lb. loaves to the property of 180 1'5 lb. the brick oven with a capacity of 450 1 5-1b. loaves, turned out five batches or 2,250 loaves, or 450 less than the electric oven. The electric oven occupies 32 sq. ft. of floor space, as against 256 sq. ft.

The coet of electricity, says the *Electrical Review and Western Electrician*, when used in the "off peak" period at Toronto, which is at night, is '5 cent per KW.-hour. The maximum energy consumption of the electric oven was 26 KW.-hours, and would cost 13 cents per hour used continuously, or \$1'3 for 10 hours' use, during which time 2,700 loaves were baked. *Pro rata*, this is equivalent to 48 cents fuel cost per 1,000 loaves, and this figure shows a saving in fuel over the brick oven of 41 cents per 1,000 loaves. The labour cost with the electric oven was less, the saving per 1,000 loaves being estimated at 22 cents.

per 1,000 loaves being estimated at 22 cents.

We gather that the bread baked electrically has a better colour and will last longer as it is not dried out as in a brick oven; moreover, the cooking conditions are greatly improved and cleaner. The electric oven is ready to bake in 35 minutes after being switched on; by its use a considerable saving in first cost of a new

bakery is ensured.

Foreign Trade. - THE MARCH FIGURES. - The following are the electrical and machinery figures given in the official returns for March:—

IMPURIS.				
Electrical goods and apparatus, excluding ma- chinery and un- insulated wire	Month . of March. £ 67,626	Inc. or dec. £ — 80,392	Three months, 1915. & 193,569	Inc. or dec. £ — 236,160
Machinery	582,088	<b>— 142,859</b>	1,774,025	- 194,190
Exports.				
Electrical goods and apparatus, excluding ma- chinery and un-			-	40.000
insulated wire	276,970	+ 25,400	<b>720,73</b> 3	<b>- 42,776</b>
Machinery	1,590,431	-1,978,168	4,539,784	<b>-</b> 5, <b>45</b> 0,164

A Lesson to Photographers.—At the Newcastle-on-Tyne Police Court on Tuesday, Lancelot Edmund Hendry, charge-man electrician, was charged under the Defence of the Realm Act with having taken a photograph in the electric shop at the Armstrong Elswick Works, without permission. Evidence for the prosecution was to the effect that on Saturday last accused was observed climbing down some pipes which cross the turbine shop, and when questioned said he had taken a photograph. He was told that he might get six months if caught, and replied: "Well, per-haps," as he walked away. Shortly afterwards he was placed under arrest and the negatives were developed. Chief Superintendent Bestwick said prisoner had not received permission to take the photographs. He was a native of Stockton and served his time with the Stockton Corporation as an electrician, afterwards with the Stockton Corporation as an electrician, afterwards going to the Sunderland Corporation. He was married and resided in Sunderland, where witness had examined his house. He appeared to be an amateur photographer, and photographs of machinery in which he was interested were found. The evidence, as a whole, was of a negative character. Defendant admitted he had done a foolish act. Photography was his hobby, and he had tried to keep a record of the places he had worked in. Apart from that he had no interest in the matter. The chairman said the case was a most serious one at a time like the present. Defendant had given no proper explanation of his action, and therefore the least the Bench could do was to impose a fine of \$20 or 51 days. least the Bench could do was to impose a fine of £20, or 51 days' imprisonment. They had taken into consideration the defendant's statement that he had no evil intention; but having regard to the evidence, the fine would have to be paid forthwith.

Static Electricity on a long Transmission Line.—
Writing to the Electrical World, Mr. C. O. Poole, chief engineer of
the Southern Sierra Power Co., says with regard to the use of
inductive reactance connected on lines to ground for bleeding off
the accumulation of static electricity:—
Several months ago, and before I knew anything of this
practice, we had a very bad case of static on a 55,000-volt transmission line that we constructed in connection with the Coaches
Valley Los and Electric Co. in the Imperial Valley. This line was built

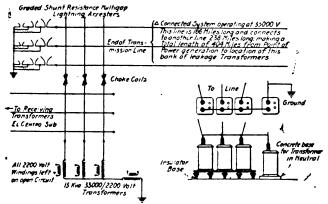

Valley Ice and Electric Co. in the Imperial Valley. This line was built on wooden poles, the conductor being of 3/0 7-strand aluminium. We used No. 351 Locke insulators, the wires being spaced on an equilateral triangle, 72-in. centres, and the length of the line

being 166 miles.
We connected this 55,000-volt line at the terminus of a 238-mile transmission system from Inyo County—connection being made at San Bernardino sub-station, this making a total transmission system from our power house at Bishop, Cal., of 404 miles.

The Imperial Valley line is operated delta at 55,000 volts.

Shortly after the system was put into operation trouble was experienced by two or three of the pole tops burning off and causing short-circuits on the system. I made a trip over the line at night in the Imperial Valley and found a great number of insulators leaking static badly, which resulted in charring the pole and to relieve the condition. I conceived the idea of bleeding at once to relieve the condition. I conceived the idea of bleeding the static off to ground, and recommended that the Holten Power Co., at El Centro, the end of the line, install four 15-kw. transformers we had in stock and connect them directly between the line and ground.

These 15-kw. transformers were wound on the primary side for 3,000 volts and on the secondary side for 2,200 volts. Three of 33,000 volts and on the secondary side for 2,200 volts. Three of these transformers were connected in star on insulated platforms, and the fourth transformer was connected between the star of the

ABRANGEMENT OF BLEEDING TRANSFORMERS.

three transformers and ground on the primary side, the secondary 2,200-volt windings being left open. The object of using the fourth transformer was to protect the 33,000-volt circuit from over-voltage in the event of ground appearing on the 55,000-volt

The effect of this installation was immediately to overcome all the difficulty with the leaking static, and the line now is as quiet and free from static as could be desired. The sketch herewith shows the arrangement of these bleeding transformers as connected to the system.

Edison to Make Benzol.—It is announced in the Elect. Rev. and Western Electrician that Thomas A. Edison has opened a factory in Johnstown, Pa., for the manufacture of benzol from coal gas, a process never before developed in the United States. Since the war began there has been a great shortage of this product.

Institution and Lecture Notes.—Royal Society of Arts.-In the list of arrangements for meetings during April and May the following appear :-

Wednesday, April 14th, at 8 p.m. T. Thorne Baker, "The Industrial Uses of Radium."
Wednesday, April 28th, 8 p.m. A. S. E. Ackermann, "The Utilisation of Solar Energy."
Wednesday, May 5th, 8 p.m. Dr. A. Vernon Harcourt, F.R.S., on "The Measurement of the Efficiency of Domestic Fires, and on a Simple and Smokeless Grate."
Wednesday, May 12th, 8 p.m. Charles R. Darling, "Recent Progress in Pyrometry."
Thursday, May 18th, 4 80 p.m. (Indian Section ) Sir Charles H. Armstrong

ryrometry."
Thursday, May 18th, 4.80 p.m. (Indian Section.) Sir Charles H. Armstrong,
"Indian Trade and War."

The paper by Mr. A. S. E. Ackermann will supplement that given before the Society of Engineers in April, 1914, by dealing with the experiments of other workers in the field.

Illuminating Engineering Society, U.S.A.—The ninth annual Convention of this Society will be held at the New Willard Hotel, Washington, D.C., September 20th-23rd inclusive. Mr. E.S. Marlow, of the Potomac Electric Power Co., Washington, D.C., is chairman of the Convention Committee.

-At the meeting of the Institution of Electrical Engineers.-

Institution of Electrical Engineers.—At the meeting of the MANCHESTER LOCAL SECTION, on Tuesday last, a paper was read by Mr. J. H. Rider on "The Power Supply of the Central Mining-Rand Mines Group." The same paper was read at Birmingham on Wednesday and in London last night.

At the annual business meeting of the SCOTTISH LOCAL SECTION held in Glasgow, on Tuesday last, the following office bearers were elected for the ensuing year:—Chairman, "Mr. David A. Starr; vice-chairman, "Mr. J. K. Stothert; chairman of Students' Section, Mr. Archibald Page: ordinary members of Committee. Mesare. elected for the ensuing year:—Chairman, *Mr. David A. Starr; vice-chairman, *Mr. J. K. Stothert; chairman of Students' Section, Mr. Archibald Page; ordinary members of Committee, Messre. J. S. Nicholson, E. T. Goelin, G. Stevenson, J. E. Sayers, A. S. Hampton, Prof. J. Cormack, *Messrs. F. H. Whysall, *W. W. Lackie, *Prof. Magnus Maclean, *A. Lindsay, *A. Wilson; hon. secretary and treasurer, Mr. Joseph Taylor; assistant hon. secretary, Mr. Wm. F. Mitchell. *New members of Committee. The annual report showed that the membership was 370, a reduction of 5 per cent. on the previous year, while the attendance at the ordinary meetings averaged 47, about the same as last year. At the ordinary meeting which followed, Mr. W. M. Selvey read his paper on "Power Plant Testing."

#### OUR PERSONAL COLUMN.

The Editors invite electrical engineers, whether connected with the technical or the commercial side of the profession and industry, also electric tramway and railway officials, to keep reuders of the ELECTRICAL REVIEW posted as to their movements.

Central Station Officials.—The Redditch T.C. has appointed, out of 106 applicants, Mr. Valentine F. Bush, of West Ham, as assistant engineer at the electricity works, at £170 per annum

per annum.

MR. H. C. ASHTON has been appointed assistant engineer at the Hammersmith electricity works, at a salary of £175 per annum.

Mr. J. Devoy, mains superintendent at the Tunbridge Wells electricity works, has resigned his appointment. The Committee has resolved to grant MR. J. E. POWNALL, chief assistant electrical engineer, a gratuity of £10 for extra work done since the commencement of the war.

MR. J. CHIRNALL, foreman fitter at the Blackpool electricity.

MR. J. CHISNALL, foreman fitter at the Blackpool electricity works, on leaving to take up an appointment with Messre. Vickers, at Barrow, was presented with a Gladstone bag, a wallet, and other gifts from the staff and workmen. Mr. W. W. Parkinson made the presentation.

MR. F. YOUNG, electrician on the Dover Corporation tramways staff, who has resigned, has been presented by his colleagues with a silver rose bowl.

MR. W. W. LACKIE, City electrical engineer, is nominated for the Presidency of the Institution of Engineers and Shipbuilders in Scotland.

MR. J. C. WILLIAMS, chief assistant and deputy engineer at the Rotherham Corporation tramways and electric light department, who is leaving to become electrical engineer and manager at Erith, has been presented by the staff and employés with a gold watch, and by the Executive Committee of the Rotherham Municipal Officers' (Wild with a got of solid silver surfacie dishes Guild with a set of solid silver entrée dishes.

Tramway Officials.—Mr. J. ELLISON has been appointed chief inspector to the Darwen Corporation Tramways. Through the war it has been decided not to fill the vacancy caused by the death of Mr. Moses Stokes, superintendent of the line. Mr. Edison will officiate in the management as deputy to Mr. Hoskens.

MR. DUGDALE, the Oldham Tramways manager, who has been ill for some time, has now resumed his duties.

General.—The vacancy in the chairmanship of the Crewe Corporation Electric Lighting Committee, caused through the death of Mr. Councillor Chapman, has been filled by the

appointment of Ald. J. H. Kettell.

The Chairman of the Council of the Society of Arts, Col. Sir Thos. Holdich, on Monday afternoon presented the Society's Albert Medal to Senator Guglielmo Marconi, G.C.V.O., LL.D., D.Sc., "for his services in the development and practical application of wireless telegraphy."

BAILIES SMITH and HANNAY, along with MR. WM. LACKIE, the chief electrical engineer, are to represent Glasgow T.C. at the twentieth annual convention of the Incorporated Municipal Electrical Association, to be held in London in June next.

MR. W. E. POTT, late general manager of Mesers. Krupka and Jacoby, Ltd., and British Graetzin Light, Ltd., of Westminster, has

been appointed manager of the Electric Novelty Department for Mesers. J. S. Hind & Co., of 6, Eldon Street, E.C., representing the Interstate Electric Novelty Co., of America.

-MAJOR S. FLOOD PAGE.—'The death occurred Obituary.on April 7th, at I overness Court Hotel, London, at the age of 82 years, of Major Samuel Flood Page, whose connection with electrical undertakings in London on the commercial and financial side dates back over a lengthy period. From the records in our side dates back over a lengthy period. From the records in our own pages, it appears that the gallant Major entered the electrical arena in the year 1882, when, in the capacity of manager of the Crystal Palace, he organised the Electrical Exhibition held there. Presumably his connection with that event gave him that com-mercial interest in electrical affairs which extended over so many mercial interest in electrical affairs which extended over so many years, for it was in the year of the Exhibition that he became general manager of Edison's Indian and Colonial Electrical Co. He left in September, 1882, for a tour abroad to prosecute the company's business in Iodia, Ceylon, Snuth Africa and the Australian Colonies. In some of these Colonies companies were started. In 1882 gas was 12s. 6d. to 15s. per 1,000 cb. ft. at the Cape of Good Hope, and very dear in India and the Colonies, and it was considered that if electricity could compete with gas at 3s. per 1,000 here it would do far better in the Colonies, &c. In this belief the Edison lighting schemes with which he was identified were launched. The Marquess of with which he was identified were launched. The Marques of Tweeddale described Major Flood Page as a "gentleman of great Tweeddale described Major Flood Page as a "gentleman of great energy," which he undoubtedly was in all his concerns whether we remember his later association in different capacities with the Edison & Swan United Electric Light Co., Ltd., with the London Electric Omnibus Co., Ltd., or with the London Chamber of Commerce. The London Electric Omnibus Co., Ltd., was formed in 1896, with a quarter of a million capital. What happened to that unfortunate concern is now more or less a matter of history—we fear forgotten, or even never known, by many men who are to-day interested in electrical vehicle matters. Briefly, it may be described interested in electrical vehicle matters. Briefly, it may be described as a concern born in advance of the times by over-sanguine men, and as one of those companies which make promises with reckless prodigality, but find themselves incapable of carrying those promises out to the stage of performance. In recent years, Major Flood Page had not appeared so prominently as formerly in electrical affairs, owing to his advancing years, but he had for a long time been on the board of three of the Marconi Wireless Companies, and was so at the date of his death. At different times in the course of his manifold activities he was described by others as anguing, enthusiastic and full of energy, and by himself as a sanguine, enthusiastic and full of energy, and by himself as a "practical business man."

PROF. W. G. ADAMS.—We regret to hear of the death, which

occurred at Broadstone, Somerset, on 10th inst., of Mr William Grylls Adams, F.R.S., F.G.S., Emeritus Professor of Natural Philosophy and Astronomy at King's College, London. He retired from sophy and Astronomy at King's College, London. He retired from that office about nine years ago. The deceased gentleman, who had reached the ripe age of 79 years, was a past president of the lastitution, he having delivered his presidential address before the Society of Telegraph Engineers and Electricians in January, 1884. In following years he was also the author of numerous papers on electrical, magnetic and other scientific matters. Prof. Adams had occupied the presidential chair of the Physical Society, and he attained considerable eminence as a mathematician and an attained considerable eminence as a mathematician and an astronomer.

HERE M. HILLER, a director of the Landsberg Kabelfabrik Gesellschaft, of Landsberg, Westphalia, is among the German officers killed in the war.

MB. L. U. VIGNOLES,-We regret to learn of the death, which MR. L. U. VIGNOLES.—We regret to learn of the death, which took place on April 6th in Argentina, at the early age of 34 years, of Leonhard U. la H. Vignoles (commonly known as "Toby"). No details are yet to hand, but he was extremely ill some eight years ago, and was believed to have a foreign body in one of his lungs. ago, and was believed to have a foreign body in one of his lungs. He then made a marvellous recovery, but was subsequently liable to chronic pneumonia, to which it is to be feared that his early death is due. He leaves a widow and two baby children. Mr. Vignoles served in the South African War, and at different stages in his career was with Mesers. Crompton, the British Westinghouse Co.. and Mesers. J. G. White & Co.

M. JEAN ANNIBAL LEGE. — We regret to learn from a correspondent (Mr. H. L. Joly, A.M.I E.E.) of the death, at the age of 74, of M. Jean Annibal Légé, a French engineer. M. Légé was associated with the electrical industry in the early days in the shops of Breguet and of Mildé, in Paris. "Later, in 1868,"

Légé was associated with the electrical industry in the early days in the shops of Breguet and of Mildé, in Paris. "Later, in 1868," says our correspondent, "he came over to London and started where Mr. W. Mackie's works were, in a yard on the east side of Farringdon Road. There he constructed the first tide-predicting machine for the late Lord Kelvin. There also, I believe, he was associated with the earlier types of are lamps, the Pilsen—and Mr. H. F. Joel will, doubtless, regret to hear of his death. For many years he was the maker of electric signalling lamps, of 'universal dotters,' targets, &c., designed in collaboration with Admiral Sir Percy Scott; in fact, only recently he was working on some electrically-controlled apparatus for the Admiralty. His inventions range from horological mechanism, somewhat lightly mentioned by Lord Grimthorpe in his book, to a dragged torpedo which anticipated the Brennan, and to petrol motors: his name is attached to a goodly array of patents. I may add that in his earlier days—45 odd years ago—he was in contact with Karl Marx and the Internationalists, and that his works have proved

haven of refuge, a stepping-stone to many a man of ability, either Briton or foreigner, just landed in London. From some 18 years of personal contact, I can vouch that no works could be found

where a greater harmony reigned between principal and worker."

MR. DAVID SMITH.—We have to announce with much regret
the death, on the 10th inst., at the age of 50, of Mr. David Smith. managing director of the United River Plate Telephone Co., Ltd., and managing director of the United River Plate Telephone Co., Ltd., and also a director of the Constantinople Telephone Co., Ltd., and London from Scotland some 20 years ago, Mr. Smith entered the service of the Electric Construction Co., and later the Electrical Power Storage Co. The late Sir Irving Courtenay, then chairman, impressed by his business capacity, selected him to fill the vacant secretaryship of the United River Plate Telephone Co. in November 1914 ber, 1914. He was subsequently appointed managing director. For some time past his health had caused some anxiety to his friends, though, until quite recently perhaps, none was prepared for a fatal termination. Highly esteemed by his colleagues, he was much respected by all who were brought into business relations with him, and those who were privileged to enjoy his friend-ship will mourn the loss of a helpful and cheerful companion, whose actions were invariably governed by high principles. Much sympathy will be felt for the widow and two young children.

#### NEW COMPANIES REGISTERED.

Elbron Metallising Co. (1915), Ltd. (139,823).—This company was registered on March 30th, with a capital of £100 in £1 shares, to take over the business carried on by L. G. Lewis at 42, Berners Street, W., as the "Elbron Metallising Co.," and to carry on the business effecting the electrolytic deposit of metals on non-metallic substances, engineers, machinists, coppersmiths, metallurgists, etc. The substribers (with one share each) are. A. C. Crowl, 15, Harringay Gardens, Green Lanes, N., clerk; S. F. Hewett, 33, Stavordale Road, Highbury, N., clerk, Private company. The number of directors is not to be less than two or more than five; the first are L. G. Lewis (permanent director and chairman) and M. Dodds. Registered office: 42, Berners Street, Oxford Street, W.

Radio Flectric Lamp Co., Ltd., (139,784)—This company.

Radio Electric Lamp Co., Ltd., (139,784).—This company on the business of manulacturers of and dealers in electric lamps and all kinds of devices for lighting or heating by electricity, electricians, electric C. M. Holmquist, 69, Leighton Road, West Ealing, W., electrica engineer; P. Adair, 163, Denmark Hill, S.E., electrical engineer. Private company. The directors are to number not less than two or more than five. C. M. Holmquist signs documents as director. Registered office: 27, Kingly Street, Regent Street, W.

Newcastle West and District Electric Light and Power Co., Ltd. (4227).—This company was registered in Dublin on March 30th, with a capital of £3,000 in £1 shares (2,000 pre£), to carry on the business of electricians, mechanical engineers, manufacturers and contractors, etc. The subscribers are:—W. Phelan, Newcastle West, merchant, 25 shares; W. A. Phelan, Galbally, Co. Limerick, merchant and farmer, 25 shares; W. A. Phelan, Galbally, Co. Limerick, merchant and farmer, 25 shares; W. Phelan, Washestown, Co. Limerick, farmer, 1 share; J. Phelan, Newcastle West, Co. Limerick, 25 shares; Mrs. M. Phelan, Newcastle West, Co. Limerick, 25 shares; Mrs. M. Phelan, Newcastle West, Co. Limerick, 25 shares; Mrs. M. Phelan, Newcastle West, Co. Limerick, 25 shares; Mrs. M. Phelan, W. A. Phelan and Mrs. B. Phelan, Qualification, one share. Registered office: South Quay, Newcastle West, Co. Limerick

Fallolite, Ltd. (139,852).—This company was registered on April 1st, with a capital of £5,000 in 4,850 pref. shares of £1 each and 3,000 ordinary shares of 1s. each, to carry on business as a lighting and heating or heating apparatus and plant, etc. The subscribers (with one share each) are: L. E. Tucker, 5, Noel Road, North Acton, W., clerk; L. P. Potter, Broad Street House, E.C., solicitor. Private company. The number of directors is not to be less than two or more than five; the subscribers are to appoint the first. Solicitor: C. R. Enever, Broad Street House, E.C. to salsbury Co., Ltd. (139,910).—This company was registered.

appoint the first. Solicitor: C. R. Enever, Broad Street House, E.C. Salsbury Co., Ltd. (139,910).—This company Was registered on April 9th, with a capital of £100 in 1s. shares, to take over the business carried on at 11, Long Acre, W.C., as Salsbury Lamps, Ltd., and to carry on the business of manufacturers of and dealers in Lamps, electricity, gas, oil and other illuminants, cycle and motors cars, aeroplanes, and hydroplanes, engineers, founders, etc. The subscribers (with one share each) are: W.D. Berry, Maxwell House, Arundel Street, Strand, W.C., clerk; Amy A. Dalton, Maxwell House, Arundel Street, Strand, W.C., clerk, Private company. The first directors (to number not less than two or more than seven) are to be appointed by the subscribers. Registered office: 11, Long Acre, W.C.

# OFFICIAL RETURNS OF ELECTRICAL COMPANIES.

Sevenoaks and District Electricity Co., Ltd.—Particulars of £15.000 debentures, created November 25th, 1914, filed pursuant to Section 93 (3) of the Companies (Consolidation) Act, 1908, the whole amount being now insued. Property charged: The company's undertaking and property present and future, including uncalled capital. No trustees.

G. H. Turner and Co., Ltd.—Particulars of £500 2nd debatures, created March 17th, 1915, filed pursuant to Section 93 (3) of the Companies (Consolidation) Act, 1908, the amount of the present issue being £360. Property charged: The company's undertaking and property, present and future, including uncalled capital, subject to £350 1st debentures. No

trustees.

Derby Lamp Works, Ltd.—Debenture, dated 24th March, 1915, to secure £6,000, charged on the company's undertaking and property, present and future, including uncalled and unpaid capital. Holders: F. W. Greaves, Derby, and J. Rae, 4, Bartholomew Lane, E.C.

Greaves, Derby, and J. Rae, 4, Bartholomew Lane, E.C.

Flather and Co., Ltd. (74,692).—Capital £3,000 in £1 stares. Return dated December 18th, 1914, 1,910 shares taken up; £1 per share called up on 410 shares; £410 paid; £1,500 considered as paid on the remainder. Mortgages and charges: £1,000.

Coast Development Corporation, Ltd.—Eight mortgages, dated March 24th, 1915 (supplemental and pursuant to mortgage dated June 24th, 1903, securing an amount not exceeding £20,000, of which £16,650 is now outstanding), charged on various properties in Felixstowe and Southwold. Holders: F. P. Matthews, Hearn Street, Curtain Road, E.C., and E. J. Bellord, 8, Waterloo Place, Pall Mall, S.W.

Montreal Tramways and Power Co., Ltd.—Particulars of 4,1,541,005 17s. 9d. (\$7,500,000) gold notes created March 10th, and secured by trust deed dated April 1st, 1915, filed pursuant to Section 93 (8) of the Companies (Consolidation) Act, 1908, the amount of the present issue being £1,438,366 3s. 3d. (\$7,000,000). Property charged: \$6,000,000 5 per cent. mortgage debenture stock of Montreal Tramways and Power Co., Ltd., 16,000 shares of common stock of \$100 each in Montreal Tramways Co., 59,000 shares of common stock of \$100 each and \$1,800,000 principal amount of the first mortgage 5 per cent. bonds of the Canadian Light and Power Co., and 1,250 shares capital stock of \$100 each in the Montreal Public Service Corporation. Trustees: Bankers' Trust Co. (New York).

London Electric Supply Corporation, Ltd. (24,957).—
Capital, £1,300,000 in 200,000 ord, shares of £3 each, 90,000 pref. shares of £3 each, and £230,000 unclassified shares. Return dated March 11th, 1915.
111,000 ord, and 89,840 pref. shares taken up; £3 per share called up on the ord, and £5 per share on the pref. shares; £782,360 paid, including £160 paid on 160 shares forfeited. Mortgages and charges, £487,355.

Pernambuco Tramways and Power Co., Ltd.—Issue on March 9th, 1915, of £25,000 debentures, part of a series of which particulars have already been filed.

Carville Site and Power Co., Ltd.—Issue on March 29th, 1915, of £10,000 debentures, part of a series of which particulars have already been filed.

Telegraph Construction and Maintenance Co., Ltd. (1,147c).—Capital, £448,200 in £12 shares. Return dated March 18th, 1915. All shares taken up; £448,200 paid. Mortgages and charges: Nil.

Lamp Manufacturing Co., Ltd. (76,151).—Capital £10,000 in £1 shares. Return dated February 4th, 1915. 5,400 shares taken up; £5,400 paid. Mortgages and charges: £2,500 debentures.

H. F. Foster and Co., Ltd.—Issue on March 31st, 1915, of £550 debentures, part of a series of which particulars have already been filed.

# CITY NOTES.

# Swiss Electrical Companies.

Swiss Electrical Companies.

The Société Franco-Suisse pour l'Industrie Electrique, of Geneva, which is closely connected with the group of the Banque de Paris, recently announced that although the electrical undertakings in which the company is interested are developing satisfactorily, some of them had not paid any interest on the loans for 1914. This statement is confirmed by the directors' report for 1914, which records gross receipts from interest, dividends, etc., amounting only to £46,000 as contrasted with £110,000 in 1913. After providing for depreciation and interest on loans of £916,000, the net profits are returned at £4,600, which sum has been carried forward, as compared with £63,000 in 1913, when a distribution at the rate of 5½ per cent. on the ordinary capital was made.

The Sweiz. Gesellschaft fur Elektrische Industrie, of Basle, which is a Swiss investment company whose sphere of activity extends to several countries, and which is associated with the group of the Siemens & Halske Co., of Berlin, reports that the company participated in 1914 in the increases in capital made by the Italian Moncenisio Hydraulic Power Co., the Petrograd Electric Lighting Co., and the Siemens Elektrische Betriebe. In addition, an augmentation took place in underwriting holdings by subscribing to new shares in various Italian and Russian companies, whilst a reduction was effected in the case of the Baku Power Co. The gross profits amounted to £193,000, as compared with £180,000 in 1913, and the net profits were £69,300, as against £69,600. A dividend of 7 per cent. has been declared on the share capital of £800,000 as in the preceding year, the total loan capital reaching £2,400,000.

## German Electrical Companies.

The Ges. fur Elektrische Hoch und Untergrundbahnen, of The Ges. fur Elektrische floch und Untergrundommen, of Berlin, proposes to pay a dividend of 4½ per cent. for 1914 on the ordinary fully-paid shares of £2,500,000, as against 6 per cent. in the preceding year, and the same rate on shares of £500,000 upon which 25 per cent. has been paid.

The accounts of the Norddeutsche Seekabelwerke, of Nordentage efter setting with £9 100 for depreciation in 1914, as

The accounts of the Norddeutsche Scekabelwerke, of Nordenham, after setting aside £9,100 for depreciation in 1914, as compared with £24,000 in the previous year, are reported to show a loss of £11,000, as contrasted with profits of £37,000 in 1913, on a share capital of £300,000. A year ago the dividend paid was at the rate of 5 per cent.

The Elektrotechnische Fabrik Max Schorch & Co., whose dividend of 12 per cent. for 1914, as against 8 per cent. in 1913, has already been announced, reports that working was fully maintained on the outbreak of the war in so far as workmen were not called up. The company had provided itself with an abundance of raw materials, and was therefore still able to carry out orders at comparatively favourable prices at the end of the year. The net profits amounted to £15,000, as contrasted with £11,000 in 1913. The methods of manufacturing had been accommodated to the prevailing conditions, and at the present time a larger number of workmen is em-

and at the present time a larger number of workmen is employed than at any other period.

The report of the Doutsche Kabelworke A.G., of Berlin-Lichtenberg, states that the undertaking was well employed during 1914 and earned larger profits than in the preceding year, these amounting to £98,000, as compared with £89,000. After deducting general expenses, taxes and interest charges and placing £14,000 to depreciation, as contrasted with £12,000, there remain net profits of £41,000, as against £34,000 in 1913. It is proposed to set aside for additional depreciation the sum of £11,000 for the machinery account, which will represent the final writing-down to one shilling of all the capital expenditure, except for sites and buildings. The sum of £4,000 has Been allocated to the special reserve fund and £3,700 to a war risks' reserve fund, and the balance permits of the payment of a dividend of 6 per cent., as compared with 8 per cent. for 1913.

The directors of the Sachsenwerk, Licht und Kraft A.G., of Dresden, state that production and turnover of the workshops, which at the beginning of the war materially exceeded those which prevailed in the corresponding period in 1913, were not very considerably less at the close of 1914 than in the previous twelve months. As gross profits the accounts show the sum of £66,000, as against £55,000 in 1913, and of the former the amount of £19,000 has been applied to depreciation, as compared with £12,500, and £15,000 been placed to the reserve fund, as compared with £18,000. The balance allows of the distribution of a dividend of 8 per cent. as against 7 per cent. in 1913. It is added that the prospects for the current year do not appear unfavourable, as orders for electrical machinery and apparatus are arriving very satisfactorily, whilst the large Army orders render it possible to maintain working in the shops without any restrictions. The directors of the Sachsenwerk, Licht und Kraft A.G., of

Indian Electric Supply and Traction Co., Ltd.— The directors' report for 1914 shows that the surplus on the year's working in Cawnpore, including £187 for interest accrued, was £12.724 (against £10 145 in 1913), and including further interest in England and transfer fees, the credit side of net revenue account shows a total of £12.758; London expenditure was £1.537 (against shows a total of £12,758; London expenditure was £1,537 (against £1,335 in 1913), and after providing £3,856 for debenture interest a net profit of £7,365 is shown. The amount brought in from last year being £940, there remains £8,305, of which the directors have placed £3,000 to reserve and £687 against the expenses of the debenture issue. They recommend the payment of a dividend of 5 per cent. for the year, which will absorb £3,901, and that the balance of £717 be carried forward. In February, 1914, a further amount of £5,000 of the 6 per cent. debentures was issued, making the total outstanding £65,000, and leaving £10,000 available for future requirements. The increase in London expenditure arises from payment of the directors' commission on the 1913 dividend, and from the low rates of exchange which have ruled during the war. The increase in debenture interest is due to the fresh issue previously referred to. Mr. D. Cruickshank, who has been a director since the formation of the company, has retired owing to ill-health, and the board have appointed in his stead Sir George Henry Sutherland.

Annual meeting: April 22nd.

Annual meeting: April 22nd.

Guildford Electricity Supply Co., Ltd.—Mr. H. P. Guildford Electricity Supply Co., Ltd.—Mr. H. Y. Smallpeice presided at the annual meeting held recently. He said that the gross receipts showed an increase of £571. The exceptional circumstances of the latter part of 1914 had, to some extent, modified the profits which they had hoped to make. After referring to the increases which had occurred in oil, waste, water and engine-room stores (£537, as against £279), wages at generating station (£885, as against £680), rates and taxes (£575, as against £405), salaries of engineer, secretary and clerks (£781, as against £519), he said that the result of their appeal against the increased assessment was eminently satisfactory, a considerable against £519), he said that the result of their appeal against the increased assessment was eminently satisfactory, a considerable reduction having been made. Considering all the circumstances they must congratulate themselves upon being able to write off £1,000 in respect of depreciation, put £250 to reserve, and pay 5 per cent. ordinary dividend, a rate which they had been able to pay for the last five years. In reply to questions, the chairman said that it was unlikely that they would require any additional machinery for the next two or three years. Reference was made to the devotion to their work of the engineer (Mr. H. L. Alderton) and the secretary (Mr. B. H. Piper). Mr. Alderton, in responding, said that the past three months had been exceptionally difficult owing to the shortage of coal, but they had managed to get through.

Winnipeg Electric Railway Co.—The report for 1914 states that the gross earnings amounted to \$4,101,302, in comparison with \$1,078,694 for the previous year. The expenses of operation, including maintenance, repairs and renewals, amounted to \$2,416,209, against \$2,252,607. The net earnings from operation therefore amounted to \$1,685,093. Of this amount the fixed charges, including 5 per cent. on gross earnings payable to the city of Winnipeg, interest on the funded debt, and other fixed charges, absorbed \$690,482, leaving a surplus for the year of \$994,611 to be added to the balance brought forward from the previous year of \$901,698, making together \$1,896,309. The usual quarterly dividends, at the rate of 12 per cent. par annum, were paid, amounting to \$1,080,000, leaving a balance at the oredit of profit and loss account of \$816,309.—Times. Winnipeg Electric Railway Co.—The report for

Great Northern Telegraph Co., Ltd., of Denmark.

—At the general meeting, which will be held at Copenhagen on May 8th, the board will propose to pay a total dividend and bonus of 22 per cent. for the year 1914, including the 5 per cent. already paid, and to transfer to the reserve and pension funds the following amounts, namely, £111,111 and £11,111 respectively.

Sao Paulo Tramway, Light and Power Co., Ltd.-The directors have declared a dividend of 21 per cent. on the capital stock.

Minchead Electric Supply Co., Ltd. — Mr. H. D. Leather presided at the recent annual meeting. He said that the year was, on the whole, satisfactory. Receipts had increased, but the average price per unit was a little down, owing to increased sales for heating and cooking, &c. The works costs showed a saving, and their cost per unit was decidedly less than that of any other works of similar size. They had added \$1,000 to depreciation and reserve, and he hoped that as years went by they would be able to build up a strong reserve fund. He would not prophesy as to the future, but the first quarter of the year showed an improvement on last year. The thanks of the meeting were given to Mr. Swarbrick (the secretary) and the staff.

Provincial Cinematograph Theatres, Ltd.—For the year ended January 31st, 1915, the net trading profit was £67,587, or £6,637 better than last year. The total distribution on the ordinary shares is 15 per cent, as against 20 per cent, for the previous year, and £9,416 is carried forward as compared with £1,131 brought in. Although the profits are larger and the theatres continue to do excellent business, a smaller dividend is declared, as a conservative policy during the continuation of the war is desirable. Two of the directors and 120 employés have joined H.M. Forces. All appointments are being kept open, and allowances made to dependents.

Canadian General Electric, Ltd.—The report for the past year states, says the Financier, that the profit amounted to \$914,527 (against \$2,029,899 in 1913), and, after deducting interest on borrowed capital, \$190,957, the net profit before providing for depreciation amounted to \$723,571. Dividends paid absorbed \$696,741, leaving a surplus for the year of \$26,830, to which is added \$913,932 undivided profits at Docember 31st, 1913, and reserve \$2,700,000, making the surplus in the balance-sheet \$3,640,762. Dividends for the year on the Common stock amounted to 7 per cent., against 7 per cent. and a bonus of 1 per cent. in 1913.

Paignton Electric Light Co., Ltd.—At the annual meeting on Monday it was reported that the net profit on the year was £720. The directors had written off £491, the remaining balance on net revenue account, and were carrying forward £229. Forty-two new consumers had been connected during the year, and the whole of the machinery and plant was reported as working very satisfactorily. The Chairman (Mr. W. J. Ham) said there was every prospect of a dividend next year.

Official Notices re Companies.—The following companies will be struck off the register at the expiration of three months, unless cause is shown to the contrary:—

Automatic Telephone Co.
Globe Code Co.
Illuminated Signs.
New Imperial Electric Lamp Co.
*Sudd Fuel (Suddite) (registered September 4th, 1911).
*West India and Panama Telegraph Co. (registered July 30th, 1869).

*Other companies with these names still exist.

Indo-European Telegraph Co., Ltd.—The directors recommend a dividend for the six months ended December 31st, 1914, of 17s. 6d. per share (making, with the interim dividend already paid, 6 per cent. for the year) and a bonus of 20s. per share, both free of income-tax; also a special distribution of 15s. per share, free of income-tax, out of interest accrued during the year upon certain investments and advance accounts.

Western Union Telegraph.—The report for 1914 shows gross revenue and income \$47,287,388, from which must be deducted operating expenses, including rent for leased plant, taxes, \$40,578,750, leaving a net income of \$6,708,638. Interest on bonds has absorbed \$1,337,243, leaving a balance of \$5,371,395.—Financial Times.

New Issue.—The London Electric Supply Corporation, Ltd., is inviting its shareholders to subscribe for £100,000 4 per cent. first mortgage debenture stock at 85 per cent., to meet overdrafts in connection with the L.B. and S.C. Railway power contracts and the general advance in demand for industrial supply.

Vickers, Ltd.—The directors have decided to place £250,000 to general reserve and to recommend a final dividend of 1s. 61. per share (free of income-tax) on the ordinary shares, making 2s. 6d. per share, or 12½ per cent. for the year. £228,876 is carried forward.

Direct United States Cable Co., Ltd.—Final dividend of 2s., less income-tax at 2s. ld. in the £, payable 30th inst., making, with the three interim dividends already paid, a total distribution of 4 per cent. for the year ended March, 1915.

Monte-Video Telephone Co., Ltd.—Interim dividend for the half-year ended January 31st last at the rate of 6 per cent. per annum on the ordinary shares.

Kalgoorlie Electric Power and Lighting Corporation, Ltd.—The directors have declared a dividend on the preference shares at the rate of 4 per cent. per annum for the six months ended March 31st, 1914.

Brazilian Traction, Light and Power Co.. Ltd.— The directors have declared a dividend of 1½ per cent. on the issued ordinary capital stock.

### STOCKS AND SHARES.

TUESDAY EVENING.

While a trifle erratic, the course of the Stock Exchange markets during the past few business days has been upward on the whole. In certain sections, more especially that for rubber shares, business is active and prices are buoyant. In American Rails, too, has occurred such a boomlet as the Stock Exchange has not seen for a year or two. As regards these last, most of the shares now changing hands are being bought by the neutrals on the other side of the Atlantic; and the quaint position will arise of no American shares being good delivery on this side before very long, except such as have been held in physical possession within the United Kingdom for six months past.

Various new issues are being made by companies able to show good cause for raising money at the present time. In the electric lighting market, for instance, a debenture issue has been sanctioned by the Treasury in favour of the London Electric Supply Co. The money is needed in order to cope with the demand from the Brighton Railway for power on the electrified portion of its system, and at 85, this 4 per cent. debenture stock is attractive largely because it is redeemable definitely at par, in 1931, instead of being redeemable at the option of the company, as in so many other cases.

There is a continuance of the demand for first-class telegraph

There is a continuance of the demand for first-class telegraph stocks and shares, and the amount of high-grade debenture stocks, for example, which is available to purchasers is almost absurdly small. One indirect result of the Treasury's refusal to sanction new issues ad lib. is to force up the quotations of existing securities, because the investor is of such a nature as a rule that he insists upon having a certain stock and no other, and will pay several points more for his particular fancy than for some other stock, equally sound, about which he has less knowledge. The which is natural enough, though it leads occasionally to such anomalies in quotations as the newspapers love to discover and proclaim.

occasionally to such anomalies in quotations as the newspapers love to discover and proclaim.

The Home Railway market is still one of the most stagnant in the House. Labour demands remain the chief bugbear of investors who might otherwise be disposed to look with a favourable eye upon the low prices to which most of the erstwhile popular stocks have descended. So far as the electrical issues are concerned, there is next to nothing going on; but within the past few days something like a free market has sprung up in London Electric ordinary shares, which are changing hands pretty freely on the basis of 31s. middle. There are inquiries, too, for the Company's debenture and preference stocks; but the other members of the electric railway group are neglected.

ence stocks; but the other members of the electric railway group are neglected.

Brazilian Tractions have benefitted substantially from the declaration of another quarterly dividend at the usual rate of 1½ per cent. on the common shares. The price rose 5½ to 59 last Saturday, came back a dollar or two in consequence of the persistent shrinkage in the Rio exchange, and again recovered. Even at the present price, the yield on the shares works out to about 10½ per cent. on the money; and it is not a little curious that the sharp rise which has occurred within the past few weeks should have had the result of tempting so few sales of the profit-taking order.

few weeks should have had the result of tempting so few sales of the profit-taking order.

Brazilian Tractions have benefited substantially from the land. Sales on behalf of Dutch proprietors are prohibited, under the Treasury regulations; while with respect to the unhappy Belgians, only such realisations are permitted as are certified to be for account of refugees requiring comparatively small sums of money with which to maintain the absolute necessities of life. With these sources of supply of shares thus cut off, and with the market now in strong hands, it may be easily seen how a little demand from fresh buyers has the effect of advancing the price rapidly.

Mexico Tramways Fives are 5 points better, and in spite of

Mexico Tramways Fives are 5 points better, and in spite of apparently discouraging news from the country, most Mexican securities have advanced this week, several of the railway stocks securing big rises.

In view of the more settled conditions of Stock Exchange markets, it has been decided to resume in a limited degree the particulars which used to be given here, before war broke out, in regard to the yields obtainable from securities quoted in our lists. The argument against such a course is that many quotations are still somewhat nominal, and that yields worked out upon nominal prices might here and there be deemed misleading. In a way, of course, this argument applied even before the war, for in those days not all the stocks were to be sold, while certain others could not be bought, and this condition of affairs varied from week to week. Weighing pros and cons, however, the present seems to be opportune for restablishment of tables of yields, and we accordingly add these figures to our lists of prices. For correction of what error may have crept into the figures we shall be grateful—which invitation, by the way, is not so much a confession of carelessness in compilation as an acknowledgment that the most painstaking efforts are not infallible in their results.

With which apologia in advance, we set out the usual list of representative securities; from these are eliminated the end-

With which apologia in advance, we set out the usual list of representative securities; from these are eliminated the end-July prices, which seem to have less practical interest that the yields obtainable at current levels. At the same time, it may be added that, should any reader wish to know the prewar price of any electrical issue, a post-card inquiry will be answered with pleasure;—

This week's dividend declarations in the Telegraph market This week's dividend declarations in the Telegraph market have had no effect upon prices, but it is satisfactory to find the Direct United States Company paying the usual 4 per cent, on its ordinary shares, while the Indo-European declares the regular 6 per cent, dividend, 20s. bonus, and 17s. 6d. special distribution, bringing the whole amount up to the usual payment. Prices are firm, and there are improvements in half-a-dozen of the leading shares. Marconis went back to 113(16) recovering between to 11 burgers. Appricant Marconis 1 13/16, recovering, however, to 11 buyers. American Matconis have sympathised with the strength of the American railroad market, and are up to half-a-guinea, though Canadians lag

market, and are up to half-a-guinea, though Canadians lag behind at just half this price.

The Manufacturing group is steady, with a good deal of business doing without alteration of prices. The Potteries Electric Traction Co. has declared a dividend of 2½ per cent. on its ordinary shares. The rubber market is still very active, although the rush of last week has subsided to a slight extent. Stock Exchange men engaged in this market find their hands full of work—much of it unremunerative, in consequence of the low prices of shares and the trifling brokerage chargeable,

though the amount of work involved is actually more than would be the case in higher-priced stocks. Prices on the whole are keeping extremely firm; and with America a more ready buyer of rubber, there is nothing unreasonable in the assumption.

boyer of rubber, there is nothing unreasonable in the assumption that the produce may further improve in price. The Armament group has been favourably affected by the declaration of a dividend on Vickers, making 12½ per cent. for the year, the same as that in the previous twelvemonth. At the present price, Vickers pay 7½ per cent. on the money.

The Stock Exchange has issued its own report within the past few days, showing a decrease in receipts of £25,000, an increase of expenses amounting to £9,800, with a cut in the final dividend from £6 to £3 per share. Electric power, working expenses and maintenance are charged in the accounts at £1,656, a decrease of £330 as compared with the previous year. It has been mentioned here before that the Stock Exchange has an electric light plant of its own, so it may be well imagined that the recent coal crisis gave the managers some anxious moments. anxious moments.

## MARKET QUOTATIONS.

It should be remembered, in making use of the figures appearing in the following list, that in some cases the prices are only general, and they may vary according to quantities and other circumstances.

Wednesday, April 14th.

# THE FRENCH ELECTRICAL ENGINEERING INDUSTRY AND ITS FUTURE.

AT a recent meeting of the Société d'Encouragement de l'Industrie Nationale, held in Paris, an instructive address was given by M. Hillairet, on the capability of France to meet the demand for electrical machinery and material. The paper was accompanied by a number of statistical tables, some of which are reproduced herewith.

Dealing first with that relating to the importation of electrical material into France, it may be noted that, although less than in 1912, France still makes relatively large purchases of carbons; these have hitherto mainly come from Germany and Austria, and are chiefly intended for arc lamps; the decline that has taken place in the importation is principally due to the increasing popularity of metal-filament lamps. Great Britain and even America have, it was pointed out, also hitherto procured part of their requirements in arc-lamp carbons from Germany, largely owing to the fact that they have been obtainable at lower figures than those demanded for the home-produced goods. M. Hillairet considers that, as regards arc lamp carbons, the four or five French works producing them could not only meet the German competition but even overcome it, were they to organise their establishments on a truly industrial and economic basis.

FRENCH IMPORTS OF ELECTRICAL MATERIAL.

	1918.	1912.	1911.
Carbons for electrical purposes	£42,640	£46,080	£26,360
Incandescent lamps—carbon fila-	·		, -
ments	2,000	5,000	16,960
" Metal-filaments	87,440	135,760	130,920
" Unmounted filaments	14,280	240	240
Dynamos	382,330	353,320	370,720
Electrical and electro-technical			.,. = -
machinery and apparatus	700,200	677,600	573,380
Dynamo parts	440	2,360	5,720
Insulated wires and cables	65,200	24,010	23,120
Armatures and detached parts of			,
same	184,480	150,080	122,240
Arc lamps and parts of same	3,200	5,000	7,820
Magnets	13,120	8,160	6,680
Accumulators and parts of same	7,160	10,600	9,440
Dry batteries	5,689	32,160	1,120

As will be seen, there was a falling-off in the importation of incandescent lamps in 1913. This was due to the fact that several works had been established in France capable of turning out 100,000 tungsten lamps per day, which gave rise, in M. Hillairet's mind, to the hope that by concentrated effort French manufacturers would soon succeed not only in meeting the requirements of the home market but also in building up a foreign trade.

The increase in the importation of armatures and magnets in 1913 is explained by the development of the French automobile industry which is a large user of such parts in connection with the ignition mechanism on petrol cars. As for dry batteries, Germany has inundated the shops, both large and small, throughout France with these in conjunction with small pocket electric lamps.

Passing to the exports of electrical material from France, these for the years 1913, 1912 and 1911 are shown below:—

FRENCH EXPORTS OF ELECTRICAL MATERIAL.

			••
	1913.	1912.	1911.
Carbons for electrical and in-			
dustrial uses	£428.200	£311,140	£210,646
Incandescent lamps	71,520	64.760	68 400
Dynamos and transformers	164,600	119,520	186,720
Electrical apparatus	583,480	122,960	369,280
Dynamo parts	40	120	280
Armatures and component parts	<b>98,40</b> 0	131,560	110,880
Insulated wires and cables	136,640	118,200	142,200
Aro lamps	11,920	43,480	123,040
Magnets	160	40	40
Accumulators and parts of same	<b>2</b> 0, <b>9</b> 2 <b>0</b>	23,560	16,760

Resulting, no doubt, from the growing demand for electrodes for electrotechnical purposes, the exports of carbons from France have shown a steadily expanding tendency. In the case of the insulated wire and cable industry, the trade showed an improvement over 1912, although the export

total recorded in 1911 was not reached. The decrease in arc lamp shipments finds its explanation in the increasing favour that is being shown towards high-intensity low-consumption metal-filament lamps. It is unnecessary to consider the tables further, as, after all, figures relating to imports and exports have only a relative value. M. Hillairet endeavoured to supplement them by an estimate, or rather an under-estimate, as he termed it, of the annual production of the French electrical industry, his figures being as follows:—

 Dynamos, transformers, &c. ...
 ...
 £2,664,000

 Electric lamps and fittings ...
 ...
 ...

 Electric wires, cables and materials for mains
 1,600,000

 Telegraph, telephone and electrical measuring instruments ...
 ...
 ...

 Accumulators, primary batteries, insulators and miscellaneous material ...
 856,000

 £8,840,000

In M. Hillairet's opinion these figures show that, with a full determination, combined with suitable action, some form of common objective between manufacturers, a wide view of commercial opportunities, a desire to meet the wishes and requirements of consumers, and with suitable endeavours to educate and instruct the latter in modern applications of electricity, French electrical material would not only be more widely used at home, but would find its way into foreign markets, both those near at hand and distant. In the lecturer's opinion France is already in possession of all the elements necessary for such an industrial development. Thirty years ago, at the outset of important applications of electricity, the position was vastly different-skilled labour was not available; raw material was not readily forthcoming; dynamo castings and armatures were made of cast-iron; the correct conditions of their use were not known; and the available steels varied greatly in their carbon content. To-day, thanks, to a large extent, to the Robert process, the progress in steel manufacture at the Creusot and Chatillon-Commentry and other works has been such that it is possible to obtain steel plates and sheets of a definite and exactly regular thickness, and precise composition and quality. The losses due to Foucault currents and hysteresis can be accurately determined and verified by actual tests. Wire mills and cable works are able to turn out material that will meet the most stringent specifications. In a word, electrical engineers now work in a well-explored field that leaves little or no scope for unexpected happenings.

France, indeed, the author claimed, now possesses everything necessary to permit of the extension and development of the electrical engineering industry in the country. He even anticipated the statement which is usually advanced, that the cost of skilled labour in France is higher than in other countries, by pointing out that this was not so serious as it was usually represented, it being only, comparing one of the largest works in France with the labour cost in Germany, the difference between the pfennig and the centime.

To make this clear, it may be stated that 1 pfennig is equal to, approximately, 1.2 centime, and that our shilling is equal to about 104 pfennigs or 125 centimes.

According to M. Hillairet, this difference can be disregarded, as, in his opinion, the cost of labour is the least important of the elements that constitute cost of production, his estimate of this being:—Labour, 20 per cent., raw material, from 50 to 60 per cent., and general expenses, from 20 to 30 per cent.

What the lecturer considered a much more important matter was the impetus that the improvement in technical methods was giving to practical applications of electricity. Originally, electrical engineering work was carried on very much in an empirical rule-of-thumb fashion, which has been largely overcome, and M. Hillairet looks forward, in the not far distant future, to seeing technical education included in the curriculum of French Universities.

The first electro-technical institute on French lines was that which, thanks to the liberality of M. Montefiore Levy, was established in Liege (Belgium), and at the head of which is M. Eric Gerard, whose teaching has had very valuable and far-reaching results, his students coming from all countries. The Liege Institute has, as a matter of fact, served as the model for those that have since been

started in France:—The Ecole Centrale, the electrotechnical schools at Grenoble, Lille and Nancy, the Laboratory and the Ecole Supérieure d'Electricité, of Paris, and the Ecole de Physique et de Chimie. It is from these schools that the French electrical engineering industry is receiving a constant stream of professional recruits.

Capital, raw material, skilled workmen and managers, and commercial leaders—France is now well supplied in all these sections of the problem. The concentration of each of these elements in a common effort should, he considers, give the French electrical engineering industry a prominent

position in the world's markets.

Commenting on M. Hillairet's address, M. Dieudonne, in La Lumière Electrique, draws attention to some points in connection with which France is not on a level with Germany, which country has hitherto proved the principal competitor in this industry. The support given to new undertakings by the banks in Germany is superior to that in France; the German patent laws, too, are better, while, from the point of view of commercialism and salesmanship, the Germans have shown that they have nothing to learn from other countries, but in this department set an example which could be advantageously followed in France. success of German electrical engineering concerns, in M. Dieudonne's opinion, is due more to active commercial enterprise than to superior technical knowledge and skill. Indeed, he does not consider that the latter is up to the French level; it may be more sectionised and specialised in Germany, but while he is not an advocate of too wide a course of training, he holds the view that too much specialising in one branch will eventually lead to a drying-up of the springs of reasoning and observation, and so hinder technical progress.

Turning to another aspect of the subject, M. Dieudonne points out that on the termination of the war, French electrical engineers will have an excellent opportunity of demonstrating that they are in a position to cope with the demands that are sure to be made upon them to replace the central stations and other electrical installations that have been damaged or destroyed during the hostilities with model plants, constructed in accordance with carefully-prepared designs and plans, and equipped with the most

up-to-date machinery.

### REVIEWS.

The Electron Theory of Matter. By Prof. O. W. RICHARDSON. Cambridge: University Press. Price 18s. net.

There are two kinds of physicists, practical and theoretical, but there is, or should be, only one kind of engineer, the practical. That is to say, the practical and theoretical are not distinct, as they may be in physics. So that the engineer is always on the look-out when he reads a book such as this one, which deals chiefly with the theory of its subject, carefully to pick out and lay to one side what he considers the more or less hypothetical portions, and to take a firm grip of those parts which promise help or advantages in actual application. What the future may bring forth to the practical man out of the mysteries of atomic astronomy is problematical, but this much can be said with certainty, that there are vast reservoirs of latent energy locked up in atomic structures, and these structures also hold secrets concerning the origin of electricity, gravitation and matter. And it seems impossible, in view of such certainties, that the engineer of to-day can afford to pass by, without trying to sieve all that is worth having from the labours of those engaged in this department of knowledge and other allied branches of pure science.

Therefore this important work by Prof. Richardson, while it contains too much of the hypothetical and theoretical for most practical men, yet also contains much that is of interest to him.

interest to him.

It is based upon a course of lectures delivered to graduate students at Princeton University. It is, therefore, not an elementary book, and is thus of little use to those whose knowledge of the facts of radioactivity is of a more or less rudimentary nature. Nor is it experimental in character, for it endeavours to deal with known quantities and to amplify and extend them by the tools of mathematics. The writer in general tries to indicate the extent to which the fundamental facts of physical science may be co-ordinated by means of the conception of the electron and the laws of electrodynamics; and with this purpose in view, in consideration of the immense field covered by the subject, he has chosen for the topics to be discussed those which seem of most importance and interest at the present time. References to scientific papers and other works are given wherever necessary.

A considerable portion of the book is occupied by a treatment of the more elementary matters, this treatment, however, being mathematical throughout. It opens with a chapter on the origin of the electron theory, and then goes on to consider electric intensity and potential, dielectric media, magnetism, electromagnetism, electromagnetic waves,

dispersion, absorption and selective reflection.

In Chapter IX the fundamental equations of the electron theory are taken in hand. Then there is an important chapter on the æther, in which the question whether the æther is at rest in the neighbourhood of moving bodies is discussed, the Michelson and Morley experiment being described with its negative result and the speculative hypotheses to explain this result. The author mentions that there is no experimental evidence of any optical effects arising from the motion of matter relative to æther or to space, and he is therefore tempted to inquire whether it is really necessary to postulate an æther for the propagation of electrical and optical effects. He discusses at length the principle of relativity, and reviews the bearing of the principle on the question of the existence of a luminiferous æther. He arrives at the conclusion that it furnishes no evidence for or against the existence of an æther, and it denies the possibility of determining the motion of such a fluid, supposing it to exist.

The chapter on "Radiation and Temperature" is very complete, and goes well into the mathematics of the subject, including dissertations on Stefan's Law, Wien's Law, the formula of Rayleigh and Jeans, Planck's Law, and so on.

Perhaps one of the most important parts of the book deals with the equilibrium theory of electronic conductors. This subject is brimful of interest and latent possibilities. Much experimental work has been done pon it, but a vast amount more remains to be done. The author takes the few laws which experiment shows to be true, and, assuming that the emission of electrons from elementary and compound substances is a purely thermal effect, sets out to discover what laws such a phenomenon should be expected to obey.

Chapter XXI on the structure of the atom reviews most of what is known about the matter up to date, and it specially deals with the stability of electronic systems under various hypotheses regarding the unknown positive element.

hypotheses regarding the unknown positive element.

A chapter on "Gravitation," that most elusive of the mysteries of matter, closes the book. The author truly says that, paradoxical though it may seem, it is quite likely that one of the chief difficulties in the way of a physical theory of gravitation lies in the extreme simplicity of known laws of gravitational action, and that any addition to our knowledge of it by experiment is scarcely to be hoped for on account of the smallness of the forces concerned; these are large enough when we deal with the enormous aggregations of matter familiar to astronomy, but they are exceedingly small with masses which can be controlled in the laboratory.—W. J. C.

The Underwar. By A. GOWANS WHYTE and T. C. ELDER. London: The Electrical Press, Ltd. Price 1s. net.

This is "a reasoned statement of the true strate gy involved in the 'War upon Germany's Trade,'" and is intended to show, without political or party motive, what measures are necessary in order to organise victory in the commercial campaign as, we hope and believe, it is being organised in the military struggle. That success can never

be attained by merely proclaiming, and again proclaiming, commercial warfare is a fact to which we have repeatedly called attention in these pages, and the authors drive it home with forceful argument and literary skill. The keynote of the book is unity of purpose -we had almost said co-operation—but it is something more than is conveyed by that expression; energetic action on the part of the Government in support of the manufacturing industries, with a view to providing security for capital invested in new industries and extensions of existing undertakings, statutory provision to ensure that all public money raised in Great Britain shall be spent in Great Britain, improved methods of salesmanship, and the practical support of the workers and their representatives, are the principal features of the authors' plan of campaign. While their proposals are not new in principle, having been advocated in our own columns, for example, for years, their book provides an admirable review of the present situation and of the requirements of the future, bringing together in a handy form the powerful arguments which have hitherto fallen on deaf ears, and concentrating their collective weight upon the mind of the reader. The question of a protective tariff inevitably crops up in the course of the work, but is dismissed as being at present hopelessly entangled with party politics; there are not wanting signs, however, that even strong upholders of Free Trade are willing, in view of the unprecedented circumstances, to modify their views, and to accept the principle of a special tariff designed to prevent the flooding of our market with German goods at knock-out prices when peace is restored. The fact that the Board of Trade at an early stage vigorously (if inexpertly) embarked upon the commercial war is welcomed as an indication that the policy of laissez faire with regard to British manufactures has been abandoned, and we may add that the decision of the Government to provide capital for the establishment of dye manufactories in this country marks a new era in this respect. We hope the book will be widely read, and will stimulate its readers to be up and doing—not merely "killing Kruger" with their mouths.

Electrical Practice in Collieries. By DANIEL BURNS. M.Inst.M.E. London: Chas. Griffin & Co., Ltd. Price

That there is a demand for a practical treatise dealing with the very important question of electrical engineering in mines is evidenced by the fact that this book, first published in 1903, is now in its fourth edition, and we quite agree with the author that "the application of electricity to mining operations extends with such rapidity that it is no easy task to keep a text-book in line with growing practice." The work is divided into ten chapters, dealing respectively with units of measurement, &c.; theory of the dynamo; the dynamo; motors; lighting; pumping; haulage; coal cutting; underground conveyors; and miscellaneous matters.

In our review of the last edition we suggested that the electrical portion of the work might with advantage be improved, and we are sorry to note that the suggestion has not been acted upon; in the present edition there are several illustrations of machines of a bygone age which we should like to see replaced by more up-to-date We think also, illustrations of representative machines. in view of the very great importance of the subject, that the question of "earthing" might be more thoroughly We can quite imagine a colliery manager or colliery engineer searching for illumination on this point, and not being much wirer after a search in the present work, and we are convinced that few colliery managers or engineers thoroughly understand "earthing." The author himself admits that the "whole question of earthing is . a most important one, and must be so regarded by the responsible person, and 'an efficient earth is not so easily obtained in a colliery as many persons imagine'"; with this we thoroughly agree, and. therefore, we question very much whether the author goes far enough when he says "short of a connection to a line of water pipes or a copper plate of considerable area submerged in water, it is difficult to obtain an absolutely

reliable and satisfactory set of conditions." We know that both water pipes and submerged copper plates have been used as "earth" in mines, and in either case with disastrous results. The whole subject of earthing should be thoroughly ventilated, especially in a book of this nature. Again, we should hesitate to recommend any colliery manager to install the "lightning arrester" shown in fig. 6, on any overhead system of wiring. The greater part of Chapter III is devoted to the D.C. dynamo, and the three-phase machine is dismissed in about two pages. The illustration on page 56 described as a "consequent" pole type might be better named, and we would point out that "Parson's turbine" should be spelt Parsons; in connection with steam turbines the test "by Prof. Ewing, of Cambridge (which) gave a steam consumption of 21.2 lb. per electrical horse-power-hour" is rather ancient history, and we question whether even a colliery manager would be satisfied with this consumption. The chapter on motors is also weak, very little attention being given to three-phase machines or switchgear. Generally speaking, the work is weak and more or less out of date from an electrical point of view, and deals more with the mechanical application of electricity; on the whole, here it is good, especially in the parts dealing with pumping, haulage, coal-cutting and underground conveyors. But is this what the colliery manager or engineer wants? We venture to think he is in search of a little more insight into constructive details, and the elucidation of the mysteries of three-phase machines, seeing that these are now in fashion at modern collieries. To the student it undoubtedly forms a valuable text-book, and the several worked-out numerical examples and the questions at the end of each chapter lend an added interest. There is room for of each chapter lend an added interest. the work—it is, in fact, badly wanted—the plan of the book is good and very mu h that is contained in it is good, but we do think that the electrical portion might with advantage be thoroughly revised and rewritten before a further edition is issued.

# TELEPHONE TROUBLES IN THE TROPICS.

THE following discussion took place at the Institution of Electrical Engineers on Mr. Liewellyn Preces paper on the above subject, an abstract of which appeared in our issue of April 9th, page 508.

Sir John Gaver said he had had some experience of trouble in 30° or 40° South latitude, where there were heavy storms, which fortunately only had ½-mile front and swept away everything in front of them. Then there was trouble with a bird which built its nest between the cross-arms, and the nest being soaked with moi-ture caused short-circuits. To overcome this trouble an arrangement of vertical wires was introduced between the arms which obstructed the entrance to the nest. Spiders were also troublesome; there were innumerable small spiders whose webs swept across the wires from pole to pole and caused short-circuits. It had been suggested that they should be swept off, but the mileage ran into thousands. Five species of beetle in the Argentine It had been suggested that they should be swept off, but the mileage ran into thousands. Five species of bestle in the Argentine perforated the lead covering of cables to lay eggs, but did not go into the paper. The author favoured filling joints with compound, which was common in the States, but not in England or South a nerica: it was almost impossible to get an insulating material coexpand in unison with the lead, and there was the danger of moisture entering. As regarded staff, the loquacity of the South American, who would exchange compliments with the operators, seriously delayed the services.

Mr. W. Cook said it was difficult to discuss the relative merits of apparatus unless the conditions were specified. He could not understand the author's attitude to the common-battery system—

mi. W. Cook said it was dimonit to discuss the relative merita of apparatus unless the conditions were specified. He could not understand the author's attitude to the common-battery system—no satisfactory service could be given when the insulation was so low that the common-battery system could not be used; the author was also not quite right in regard to Mahommedan women operators, as these were employed in Constantinople, the only concession to them being a head covering. He was glad to see the remarks in regard to filled joints, as money was often lost by pumping air into the cable, &c.; poles made from discarded steel rails gave a tisfactory results, and he had used concrete poles costing half as much as Hamilton poles. The first cost of covered work was often more than compensated for by decreased maintenance. As regarded humidity, some Scarborough records appeared to be almost as bid as those mentioned; at Falmouth 90 per cent, was recorded regularly in the early mornings of July and August.

Mr. W. SLINGO, referring to the author's remarks on the magneto system, said the central-battery system had proved its reliability and utility in service, and if difficulties arose steps should be taken to overcome them. The automatic system seemed the most appro-

priate in a place where there was language difficulty, and it was not more difficult to maintain than the common-battery system. Enamelled coils were being tried by the G.P.O., after being subjected to rigorous tests. An automatic telephone for 700 lines had been installed at Simla, and found more popular and rapid in service than the old system, and this was to be extended.

MR. J. E. KINGSBURY said he had thought that experience with enamelled wire would have enabled some troubles to be got over; as an instance, he cited the case of wool-covering of a multiple switchboard cable, which was attacked by moths. He agreed with the author's remarks on solid joints; air drying-out was something of a luxury. Trouble arose at the joints, and the solid joint appeared to get over the difficulty. The author appeared to be taking the risk of allowing primitive man to put up with to be taking the risk of allowing primitive man to put up with primitive appliances.

MR. WEIGHTMAN said troubles due to heat and humidity were most felt when such conditions were practically constant throughout the year. Red fibre, leather and uralite used in home practice were quite unsuitable in the tropics, although there were areas in the tropics which were infinitely better from the insulation point of view than the temperate zone.

MR. LAIDLAW remarked that the paper covered two-thirds of the globe. Did the author mean that the type of equipment mentioned would be suitable for all localities? Possibly teak was the best would be suitable for all localities? Possibly teak was the best wood for use in the tropics. If wires were run through trees, it was possible that the common-battery would not work at all, but even with poor insulation some sort of service could be obtained with a mageto system; each case must be decided on its merits. The author did not prove that enamelled wire was wrong, and probably in moist places the coils could be sealed up and so protected. and so protected.

A. J. STUBBS had always been impressed with the difficulty of getting an accurate idea of the troubles of engineers in the Colonies and tropics. If they would carefully report their difficulties, engineers at home could probably assist them. He believed it was usual in the States to have special magneto extensions for long distances; they did not attempt to use the common-battery

system for that purpose.

MR. McAlpine said lines which followed tropical coasts, subject to monsoons, were encrusted with salt all the time. Iron had to be replaced by teak, and owing to the rapid corrosion of iron wire 400-lb. copper-wire was used. Copper-clad steel wire had been tried, but its life was less than three months. Washing was the best way to get rid of the salt; oiling seemed to increase the trouble. In a hill country other extremes were met; it was very dry, but owing to the contour of the land long spans were necessary.

dry, but owing to the contour of the land long spans were necessary, eight poles to the mile, and a wire spacing of 24 in vertically. Transportation facilities affected the type of pole used; he had used Hamilton steel poles, and found old railway rail poles cheaper locally than any others. One difficulty in the introduction of new things in native country was the local jealousy; if a new instrument was installed for a subscriber all the other instruments developed mysterious faults and would have to be replaced. He had tried many varieties of enamelled wire, and in every case it broke down in a few weeks.

Mr. H. Laws Webb said it was idle to discuss the type of central office equipment if they did not know the number of subscribers and probable growth of the system. Troubles were due to the climate, to neglect of standard practice, and to the subordinate position of the telephone, owing to its being under (3 overnment control. Many difficulties would be overcome by using aerial cable, and this was nearly as cheap in the case of several wires as open lines. Steel cased instruments might be used. He asked whether the author had noted rough usage of the apparatus, and suggested that ignorance of the subscribers was due to neglect in not educating them. In Constantinople they were rather surprised to find that Mahommedan girls had offered to be operators. He believed that glass insulators were largely used in the States.

Mr. G. H. Nash thought that every engineer in the tropics

the States.

MR. G. H. NASH thought that every engineer in the tropics formed his own opinion because there was no central point of information. There were hundreds of questions involved in design to which answers were required by the manufacturers.

MR. WALKER considered that microphones should be damp-proof in all cases, as the diaphragms got damp and dull. Aerial cable was eminently suitable for long-distance work, and almost as cheap as open circuits. Oil in insulators got coated with dust, and oil insulators were no better than double-petticoated insulators in oil insulators were no better than double-petticoated insulators in

MR. H. HARBISON said they were getting over the difficulty of evenly coating enamelled wire, and such wire, silk-coated and impregnated, was being used in telephone instruments with

MR. SEMBY said he believed in metal casing for instruments, but care had to be used to avoid rust. Fibre, ebonite and hard rubber insulation gave trouble in the tropics; the receiver should have a metal cap; and all pole pieces should be lacquered to

prevent rust from touching the disphragm.

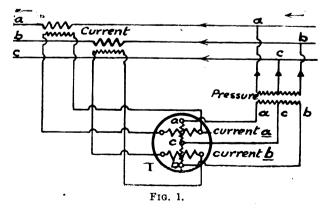

The author, in replying, said the paper referred to really tropical countries, such as Uganda, the Malay States, &c., which were forest regions. In no case were the switchboards really comparable in size with English boards; the largest would be for 1,500 lines, and the usual size—say, 500 or 600 lines. This made all the difference in the abelia of system and rephare this condition had difference in the choice of system, and perhaps this condition had not been made clear. Mr. Alexander Siemens said that for the Indo-European telegraph lines iron poles were used, and to protect them from wandering camels a trench was dug round the base of the pole and the excavated material heaped up in conical form round the pole in the centre; this practice was also followed in the Soudan.

# CORRECTING ERRORS IN POWER MEASUREMENT BY THE TWO-WATTMETER METHOD.

The extensive and ever-extending use of three-phase current renders its correct measurement by commercial instruments a matter of great importance. Improvements in wattmeter and watt-hour meter construction and testing have been such that errors of instrument-law and calibration are easily kept within narrow limits prescribed by statute and the needs of practice. Where, as is usually the case, a two-element meter is used to measure three-phase power by the two-wattmeter method, incorrect connections are frequently made, and these if undetected introduces connections are frequently made, and these, if undetected, introduce errors far in excess of those dependent on inherent defects in the instrument itself. The increasing energy demand of industrial consumers and the extending use of high-tension distribution combine to increase the risk of mistaken connections, for both current and pressure transformers are used between high-tension. current and pressure transformers are used between high-tension, heavy current networks and three-phase meters, and in a circuit, as shown in fig. 1, there are no fewer than 27 possible permutations of meter connections, only one of which yields accurate readings under all conditions. As shown by the subjoined table and the

Permutation.	cont	ecte	phase ed to (fig. 1).	flow in	tion of current oil.	Ratio a

curves in fig. 3, there are 10 permutations which yield correct meter readings at one particular power factor, and the danger is that a wireman who makes some mistake in connections, evident by the faulty running of the meter, may then commence to inter-

change leads (instead of tracing all leads back to the mains), and thus hit on a permutation which gives approximately or even absolutely correct readings (within the limits of instrument error) at the particular power factor of the load tested, while leading to very erroneous readings at other power factors. The connections shown in fig. 1, and these alone, are correct for a double-element three-phase meter using current and pressure transformers. With correct pressure connections, and with each of the five incorrect permutations of pressure connections shown in fig. 2 (II—VI), there are four possible arrangements of the current connections, viz.: Correct; phase a reversed; phase b reversed; both a and b reversed. In the table and fig. 3, those three cases are also taken into consideration in which, the pressure connections being correct, each pressure phase in turn is broken.

With correct meter connections, and assuming (what is sensibly the case in practice) that load and pressure are balanced between shown in fig. 1, and these alone, are correct for a double-element

phases, the meter reading is proportional to the product  $\sqrt{3}$  I E  $\cos \phi$ —where I and E = effective current and pressure per phase and  $\cos \phi$  = power factor of demand. The ratio R of the actual

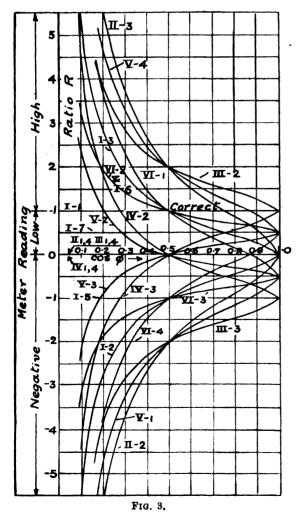

reading to the true reading in each of the 27 permutations specified above, is shown in the foregoing table.* In columns 2, 3 and 4 are shown which pressure phases are actually connected to the terminals which should carry phases a, b, c.

Columns 5 and 6 indicate the direction of current flow in current

coils, phase a and b, + denoting correct and — denoting reversed

coils, phase " and ", flow.

Values of B for various values of  $\cos \phi$  are shown by the curves in fig. 3, the key numerals attached to which correspond to those in the above table. If the meter reading is at all times zero (as in permutation II, III, IV, cases 1 and 4), or if the reading is at all times negative (as in cases I—2, 4; II—2; III—3; V—1; and VI—3), the fact that the meter connections are wrong is at once

obvious, but there remain 14 permutations under which the meter runs in the correct direction but at incorrect speed. In the four cases I—5, I—7, V—3 and VI—4, the reading is incorrect at all power factors, hence the mistake is at once disclosed by com-

paring the meter reading with that of a standard instrument. In the 10 remaining cases, however, R = 1 at a certain power factor which is: 0'2 in case V-2; 0'28 in case IV-2; 0'5 in cases I-3, 6; VI-1, 2; 0'76 in case II-3; 0'87 in case V-4; and 1'0 in cases III-2 and IV-3. At all other power factors the reading differs from that of the standard meter, hence, by testing at say 1'0 and 0'5 power factor, mistaken connections will inevitably be detected.

When the load power factor is approximately known, the curves in fig. 3 enable at least approximate correction to be made in the actual reading of a meter found to be connected incorrectly after it has been in service for some time. At least the incorrect indication can be made a basis for payment by agreement. In many cases the value of R, during comparison with a standard meter, gives a clue to the mistake made in the connections, but in all cases of doubt the latter must be traced and checked throughout. Mere trials of various interpositions of leads may yield fortuitous and misleading accuracy over a restricted range of power factors.

# RUSSIAN CUSTOMS DUTIES ON ELECTRO-TECHNICAL PRODUCTS AND ON THEIR RAW MATERIALS.

UNTIL now, says an article in the Russian Government Gazette, the Russian electrotechnical industry has mostly used foreign machines, apparatus and materials. Germany has been the principal furnisher of these to Russia owing to her (Germany's) highly developed and intensely specialised industry. For the moment the importation movement from Germany is stopped, and moment the importation movement from Germany is stopped, and Russia is experiencing a great shortage in many articles to which the country has become accustomed, but the production of which was not effected at all in the country, or was only in the primitive stages. There is a widely spread idea that many of the products of the electrotechnical industry are not produced in Russia because of the existing Customs tariff. Consequently it will be interesting to explain in what degree the action of the existing tariff which was introduced on February 16-29th, 1906, has been effective, whether on the importation of foreign products, chiefly from Germany, or on the corresponding production of such chiefly from Germany, or on the corresponding production of such products in Russia.

Taking the electrotechnical industry comprehensively, it must be admitted that some of its branches are firmly established in Russia, and quite satisfactorily supply the demand, whilst othera, if established, only partially supply the market, and the balance wanted is made good by a more of less important importation. Of the goods the production of which is firmly established Russian industry, we have

industry, we have-

1. Iron and copper wire, conductors and cables.

2. Electric accumulators.

3. Telephone and telegraph apparatus.

4. Insulating materials, &c.—largely porcelain goods.
Without dwelling on the production of iron wire which is
usually employed only for telegraph and telephone lines, and is
made exclusively in Russia, it is not without interest to observe
the relative extent of the importation and of the inland production

or the Koods use	Duty.	of					
	Imp Poods.	orted. Roubles.	Made i Poods.	n Russia. Roubles.	Roubles per pocd.	duty to value.

telephone apparatus	5,900	178,000		4,367,000	9 r.	25.8	

The principal materials used in the production of the goods named in the above table are copper, lead, and brass. The duty on named in the above table are copper, lead, and brass. The duty on copper bars is 5 roubles per pood, and the average price abroad in 1912 was 11 roubles per pood, i.e., 45 per cent. The duty on lead is 70 copecks per pood. The average price of lead abroad was 2 roubles 90 copecks per pood, i.e., the duty equals 25 per cent, of the cost. The duty on brass depends on the composition of its manufacture, and ranges between 5 roubles and 7 roubles 10 copecks per pood; and it works out at about 45 per cent. of the cost, like the copper duty. The following tables show the duty on the raw material to be about the same as on the finished article per pood: finished article per pood :-

	D	uty on aterial.	Per cent. of cost.	Duty on finished product.	Per cent. of cost.

^{&#}x27; See also Schweiz, Elek. Verein Bulletin.

How the furnishers of goods adjust their prices to the cost of corresponding imported goods is shown with regard to copper. The average price of electrolytic copper abroad was 11 roubles per pood. In Russia the price of Russian produced electrolytic copper was 16 roubles per pood; the duty is 5 roubles per pood. Brass again, which is sold only in rods or bars and sheets, is usually dearer than pure copper. Thus, the price of average brass in 1912 was 17 roubles 36 copecks per pood, which, with a duty of 6 roubles per pood, gives us the cost of brass as 11 roubles 36 copecks per pood.

It is obvious that foreign factories have their copper and brass

It is obvious that foreign factories have their copper and brass much cheaper than the Russian factories have them, the difference being just the amount of the Customs duty. The conclusion naturally is that we should reduce the duty on the raw material and increase the duty on the finished product in order to encourage

home industry.

The foregoing shows the producers of the crude and the finished products to have opposing interests. A high tariff means high prices; but in any case it stimulates the production. Efforts must be directed to establishing a home industry built on raw material of home production. The working of the tariff is shown in connection with copper as follows:—

By the tariff of 1891 copper paid 3 roubles 75 copecks per pood. Whilst the tariff endured—till 1903—the production of copper in Russia increased when the price of copper reached 12 roubles 95 copecks per pood, and decreased as soon as the cost of copper in Russia had to be reduced below this level as a result of reduced.

in Russia had to be reduced below this level as a result of reduced

prices abroad.

Data on existing Russian copper deposits showed that the production of copper would grow with the price of the metal no lower than that named. The progress of the copper-producing industry in Russia after the introduction of the tariff of 5 roubles per pood in 1906 is seen in the following table:—

Year.		Poode.	Year.		Poods.
1903	•••	564,000	1908		1,033,000
1904	•••	600,000	1909	•••	1,334,000
1905	•••	519,000	1910		1,378,000
1906	•••	571,000	1911	•••	1,564,000
1907	•••	875,000	1912		2,047,000

The quantity of copper imported is much lower than that of the national production; thus in 1911, the copper imported amounted to 447,000 poods, and in 1912 to 429,000 poods.

As to lead, whether for cables or accumulators, it paid 37.5 copecks per pood by the 1891 tariff; but by the 1906 tariff, now in force, it pays 70 copecks per pood. But neither tariff has seriously stimulated the home production of lead. When the tariff seriously stimulated the home production of lead. When the tariff was 37.5 copecks per pood the importation of lead rose from 1,880,000 poods in 1900 to 2,899,000 poods in 1903, and fell back to 2,468,000 poods, and rose to 2,879,000 poods, in 1904 and 1905 respectively. Under the 70 copecks per pood duty the importation rose from 1,304,000 pood level, to which it had fallen in 1906, to 3,099,000 poods in 1910, fell to 2,537,000 poods in 1911, rising again to 2,722,000 poods in 1912.

If we remember that in 1912 Russia produced only 82,121 poods of lead, notwithstanding the abundant deposits of lead and silverlead ore in the country, the ineffectiveness of the duties imposed becomes obvious. It is proposed to raise the import duty to 1 rouble 10 copecks per pood. Further, the Customs duty does not middiently protect the finer wires and conductors; so, bearing in mind the prices of raw materials, we arrive at the following Table

mind the prices of raw materials, we arrive at the following Table

of duties:

, -	Existing duty per pood.	Proposed duty per pood.
Copper-wire from 12 mm. to the smallest gauge	7 r. 35 c.—11 r. 85 c.	8 r.—14 r.
Conductors, various	16 r. 20 c.—17 r. 70 c.	16 r. 20 c.—20 r.
Electric cables	6 r. 70 c.	7 r. 10 c.
Electric accumulators	9 roubles	14 roubles
Telegraph and telephone		,
apparatus	9 roubles	30 roubles

The consumers' interests in the matter of reduction in price The consumers' interests in the matter of reduction in price must be found in competition inside the country. The article holds out little hope of lower values for raw materials. But it is different with finished products, such as, for example, cables and accumulators. The existing cable works in Russia are syndicated under the name of "Elektroproyod," the leading house being the Russian United Cable Factories, which is the largest cable and conductor-producing concern in Russia. Unfortunately with the lion's share of the business, it cannot be called Russian. It exists on German capital. The production of accumulators is similarly circumstanced. It has been monopolised recently by the Russian Tudor Accumulator Factories—a German concern that dictates the prices Accumulator Factories—a German concern that dictates the prices of accumulators on the Russian market. Therefore every new of accumulators on the Russian market. Therefore every new accumulator factory is welcomed such as the Morgulius, of Odessa.

accumulator factory is welcomed such as the Morgulius, of Odessa, and the Recks, of Petrograd. Government orders should be given in preference to Russian—and certainly to non-German—houses.

Another series of electrotechnical goods, the production of which has not been sufficiently established in the country, is listed in the following table. These used to be imported, mostly from Germany, either complete or in parts, to be assembled in Russian factories, founded on German capital.

Respecting dynamo machines, electro-motors and transformers made in Russia classified particulars have not been received and in

Respecting dynamo machines, electro-motors and transformers made in Russia, cla-sified particulars have not been received, and in the sum of 12,000,000 roubles are included parts of the respective items and discharge mechanisms. The term "none," in the table, means hardly any, if any at all. It has been difficult to estimate an average per cent. of duty for raw materials and finished products. Copper averages 9 per cent. to 16 per cent. in all machines; in transformers it is 20 per cent. to 30 per cent. In view of the

numerous other constituents, it becomes almost impossible to estimate the part played by each.

Dynamo machines and electro- motore of all kinds Electric trans- formers		5,888,000			Duty per pood.  8 r. 60 c. 8 r. 50 o	value.

Electric switches, fuser, rhoostats, bells, signal fis- tings, &c. Electrical measur- ing apparatus Electrical incan- descent lamps.  Units	140,000 26,000 80,000	8,860,000 1,189,000 — 8,960,000	none none carbon— 2,186.000 metal— 525.000	885,000		97 } 30
· · · · · · · · · · · · · · · · · · ·	20,000,000	-,0,000	,	,		

Therefore, the most correct measure of duty is obtained by s Therefore, the most correct measure of duty is obtained by a comparison of the cost of these goods with that of corresponding foreign, and especially German-made, manufactures. This shows that the existing duty of 8 roubles 50 copecks per pood is sufficient protection for the production of high-power dynamo machines and electromotors, in which cast-iron, iron and steel are largely used, but scarcely protects at all the production of small (20 pood) dynamo machines, electromotors, and transformers: therefore, the duty on these should be increased.

The production of electric switches keys fuses sockets.

The production of electric switches, keys, fuses, sockets, rheostats, bells, &c., it has proved impossible hitherto to establish in Russia. The duty of 9 roubles per pood is not high

enough.

Any production there is of electrical measuring apparatus in Russia is on a very small scale in Petrograd and Warsaw. It is calculated that the cost of production of the simplest types of measuring instruments is about 180 roubles per pood against 150 roubles in Germany; therefore, an import duty of 30 roubles per pood is required on these goods.

There are now two duties on electric incandescent lamps, 30 roubles per pood with carbon filaments, and 65 roubles per pood with metallic filaments. These rates are sufficient, making 6 copecks each on carbon-filament lamps and 13 on metallic.

The writer of the article, Prof. A. Kuznetzoff, here furnishes a table of the before-mentioned goods, showing the importation or

table of the before-mentioned goods, showing the importation or protective duty at present levied on them respectively, and the duty that should be levied in order to ensure efficient protection.

W. 10-		

The writer concludes his article with the observation that higher duties alone will not necessarily create the desired industries in Russia. If not accompanied by a series of practical measures, which he enumerates, the result, he says, may simply be to make the products dearer in Russia.

Prices Advance. — THE STERLING TELEPHONE AND ELECTRIC Co., LTD., of 210-212, Tottenham Court Road, London, W., announce an advance of 10 per cent, in most of the prices given in the ninth edition of their catalogue and in current publications.

# MAIN-LINE SIGNALLING ON RAILWAYS.

By W. C. ACFIELD.

(Abstract of paper read before THE INSTITUTION OF ELECTRICAL Engineers at Birmingham, March 31st, 1915.)

THE object of the system of block telegraph signalling is to THE object of the system of block telegraph signalling is to prevent more than one train being in the section between two block signal-boxes on the same line at the same time, thus providing an adequate interval of space between following

Prior to 1875 the block telegraph system and interlocking of points and signal appliances were worked independently of one another, but a combined lock and block system was introduced which replaced it interests to be a signal appliance. one another, but a combined lock and block system was introduced which rendered it impossible for a signalman to accept a second train until an electric treadle, operated by the passing of a train over the railway, unlocked the block instrument in the train-on-line position.

There are certain limitations to its adoption as sufficient

There are certain limitations to its adoption, as sufficient elasticity cannot be obtained in cases where passenger, goods, and mineral traffic are concerned. In goods and mineral

ing of a train over the latinary, the ment in the train-on-line position.

There are certain limitations to its adoption, as sufficient There are certain limitations to its adoption, as sufficient There are certain limitations to its adoption, as sufficient There are certain limitations to its adoption, as sufficient the least of the defection of the sufficient of the latinary and interest and mineral traffic are concerned. In goods and mineral working it is not necessary to have so large a margin between trains as in passenger-train working.

To enable closer working to be carried out a mechanical arrangement is provided, viz., the cancel key, in the use of which there is unfortunately no check upon the signalman. By injudicious use of this key several serious collisions have soccurred. This is the weak spot in a lock and block system. The treadles in use to-day are of the mercury type, which are far preferable to the old form of rubbing contact. The mercury is contained in a box or chamber, and is set in motion by the deflection of the rail to which the treadle is attached. The interlocking block is a form of lock and block in use to a large extent on the Midland Railway (which railway it is the author's privilege to serve), and furnishes the necessary elasticity for passenger and goods traffic. The instrument used elasticity for passenger and goods traffic. The instrument used is known as the rotary block; the handle stands normally vertical in the "blocked position," and to give the "line vertical in the "blocked position," and to give the "line vertical in the "blocked position," and to give the "line vertical in the prevent a signal being given a second time unless the handle has been rotated to both the "line clear" need to prevent the handle being turned in a reverse direction, and this prevents a signal being given in a reverse direction, and the rotary signal lever in the rear is placed to danger. After "line clear" has been given by the first movement, the handle is then turned to the "train on line" danger position before the home signal can be used a second

time.

The rotation locking referred to provides that the home signal pulled over and replaced becomes locked until the starting or shunting signals, where the latter exist, have been pulled over and replaced; and upon the completion of this operation the starting signal is once more automatically electrically locked by the advance section, and is only released by trically locked by the advance section as before the clear being given from the advance section as before described.

described.

As it is necessary to provide means whereby the signalman can wipe out one or other of the block indications, pressbuttons are provided on the instruments in the advance section and the rear section; and it is only by the co-operation of the two signalmen pressing their respective buttons simultaneously that "line clear" can be cancelled. The action of the two signalmen lifts out the ratchet lock, and enables the handle to be turned in a backward direction to "line blocked." Even this operation cannot be performed unless the starting signal in the rear is at danger, and it thus affords additional safety in working.

The cancelling of "train on line," which may be necessary owing to an on-coming train unexpectedly having to shunted in the rear section, after permission has been given for it to leave that section, or on account of the treadle having

shunted in the rear section, after permission has been given for it to leave that section, or on account of the treadle having failed to release the block instrument, is quite a different problem. To prevent the cancel being used without a record being made, it is masked by a glass, which has to be broken before the cancel button can be used.

It is the practice now to provide electric repeaters more generally to distant signals, irrespective of the facility with

which the latter can be seen, in order to give the signalman an indication of the working of the signal. Home, starting, and other signals are also electrically repeated where they are out of sight of the signalman. These electric repeaters are preferably of the 3-position type, showing "on," "off," and "fault." Where signal lights cannot be seen by the signalman at night-time light indicators, electrically operated on the pyrometer system by the expansion bar placed over the flame of a signal lamp, are also provided in signal-boxes, but are not at the present time generally adopted.

Mr. A. T. Blackall has mentioned a device for interlocking the distant signal with the block telegraph system by making use of the electric repeater circuit; this ensures that the distant signal must have gone to the danger position after the passing of one train and before the acceptance of another.

Train stops for emergency purposes have been suggested

signal must have gone to the danger position after the passing of one train and before the acceptance of another.

Train stops for emergency purposes have been suggested by the Board of Trade as a means of arresting trains running past signals at danger. It is comparatively easy to provide them on electrified railways where the speed does not exceed 40 miles per hour, but in the case of steam railways, or even electrified railways where the speed may be anything from 40 to 80 miles per hour, it becomes increasingly difficult to design any appliance of this type that will stand the shock of impact, and at the same time meet with the requirements of express traffic working. No known automatic train-control apparatus of the mechanical type can be considered to be satisfactory.

The author suggests that a cab-signalling device is the solution of the problem; but it is considered undesirable for any indication beyond an audible signal to be given to the driver.

Probably one of the most important appliances introduced into railway signalling in the past few years is the system of track-circuiting the lines of railways, the use of which has enabled innumerable difficulties and problems to be solved, and gives very adequate protection to traffic working generally. It is used not only in automatic and power signalling, but also with very great advantage in manual systems of interlocking, by which it is possible not only to utilise the running lines to perform the indication of the presence of trains and vehicles, but to safeguard such trains by operating electric locking on signals, and also to operate electrically signals in automatic and semi-automatic systems on such sections of railways over which track circuit extends.

The essential feature is a section of track insulated at each end from adjoining sections of the track, each rail in the

The essential feature is a section of track insulated at each end from adjoining sections of the track, each rail in the section being connected together by bond wires for the purpose of making a continuous conductor from one end of the section to the other. At one end of the insulated track section a battery is provided, the positive terminal being connected to one rail and the negative terminal to the other. At the entering end of the section a relay is connected to the rails in a battery is provided, the positive terminal being connected to one rail and the negative terminal to the other. At the entering end of the section a relay is connected to the rails in a similar manner; thus a path is given from the battery along the rails on one side, through the relay and back through the rails on the opposite side to the battery, and by such connection the relay is continuously energised so long as the track is unoccupied. The presence of a pair of wheels or a train in the section short-circuits the battery, causing the relay armature to drop. A broken rail will open the circuit and de-energise the relay, and the fact that the track circuit operates on the closed-circuit principle renders it very reliable, as any failure is on the side of safety. The relay armature is attracted on the passage of the weak current (necessary only for its operation) of the track circuit, which operates an indicator or electric lock, or controls the motor for working a signal. The armature carries a number of contacts which can be made to close as many different local circuits as desired. The relay, as constructed to-day, consists of very few parts that can get out of order, is easy of adjustment, and although placed in a case at the side of, or between, running lines of railway, is not influenced by the vibration caused by passing trains.

The type of insulated joint used on the Midland Railway is nown in fig. 1. The insulating material on each side of the trains. snown in fig. 1. The insulating material on each side of the fish-plates, between the rails, and in the bushes around the bolts, is compressed fibre, and standard-pattern fish-plates and bolts are used, so that it is possible for any platelayer to replace the insulation without any difficulty.

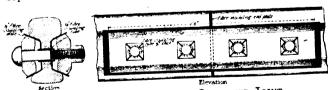

Fig. 1.-Midland Railway Insulated Joint.

Owing to the difficulty of applying continuous-current track Owing to the difficulty of applying continuous-current track-circuiting to meet all requirements, alternating-current track-circuiting has made rapid progress of late years, and now appears likely to supplant the continuous-current system in appears likely to supplant the continuous-current system in this country. The A.C. track-circuiting can be rendered absorbable in the form the effects of stray currents, even from an A.C. power supply, and in some cases is cheaper to install than continuous-current track-circuiting; moreover, it is said to be easier to maintain, especially on electrified railways. On electrified railways the track circuits are sanctioned by the Board of Trade to supersede the locking bars on facing points, and the track circuit electrically locks the facing points

in whichever position they are set for the trains to pass over, the signal lever governing the route being electrically backlocked until the train has passed the overlap of the section, so that as long as the track circuit is occupied the points cannot be moved until the train has cleared the track.

The adoption of track-circuiting has necessitated greater co-operation between the permanent way and signalling staffs in maintenance work. The action of changing crossing and ordinary rails becomes equivalent to the disconnection of signalling arrangements, and the rules for permanent-way operations and disconnection, although practically distinct from one another in the past, now become so closely allied that one depends on the other if safety is to be maintained.

Platelayers' lorries require special attention where a track circuit exists, and before they are placed upon or run over any

circuit exists, and before they are placed upon or run over any portion of a line that is track-circuited the permission of the signalman to whose signal-box the track circuit is connected must be obtained, owing to the fact that lorries cannot be relied upon, particularly if unloaded, to short-circuit the track so that signals are set at "danger," or to operate the electric

locking on the signals.

The problems before all railway companies to-day for the prevention of accidents may be put down under the following

two headings:

(a) Protection of trains detained at home or starting signals.(b) Prevention of drivers running past signals at danger. The author suggests that they can be met by appliances such as are now being installed on the Midland Railway.

such as are now being installed on the Midland Railway. Protection of trains detained at home signals.—A rotary interlocking block is provided between the home signal of one section and the starting signal in the rear, the latter signal being electrically released by the pegging of "line clear." After "train on line" has been pegged, the block instrument remains locked in the train-on-line position until the train accepted has passed the home signal and has operated an electric treadle ahead of such signal, the operation of which by the train frees the block instrument, as described earlier in this paper in lock and block systems. This appliance is used on the most important lines, but in cases of cless important lines a "train waiting" arrangement is used, as described later.

described later. 'Another arrangement is used where trains are detained at Another arrangement is used where trains are detained at home signals out of sight of the signalman. In this case a short length of track circuit is provided, outside the home signal, which indicates the presence of a train and holds the block indicator (for the section thus occupied) in a train-online position until the train has passed off the track-circuited line.

line.

Protection of trains detained at starting signals.—The whole length of the line between the home and starting signals is track-circuited, and when occupied not only gives a visual indication of the condition of the line to the signalman, but also electrically locks the home signal or signals leading on to that line, thus preventing the signal being used again until the track is clear. The problem of track circuits for this function becomes more complex where junctions occur. For every junction or additional junction between home and starting signals, the running lines must be subdivided into separate every junction or additional junction between home and starting signals, the running lines must be subdivided into separate track circuits in order to give the necessary freedom in traffic working without overlocking the signals for parallel routes. According to the subdivisions of the tracks the various signals are locked by one or more track circuits; in some cases a signal being locked by as many as three and four tracks. Cases of less important lines are met by providing a treadle ahead of the starting signal and an electric lock on the home signal, so that after the home signal has been lowered and replaced to danger it becomes locked in its normal position until the treadle ahead of the starting signal has been operated. Special mechanical locking is provided on the levers working

Special mechanical locking is provided on the levers working these signals so that it is necessary for the home signal to be restored to danger before the starting signal is replaced; and similarly the starting signal has to be replaced to danger before the home signal can be used again. This arrangement, in con-junction with the interlocking rotary block, ensures the signals being at danger before another train can be accepted on the

block instrument.

Train-waiting arrangement.—This is an audible and visual system, and enables a fireman to inform the signalman that his train is waiting at a signal. A plunger and an electric horn are fixed on a cast-iron column near the signal, and, on horn are fixed on a cast-fron column near the signal, and, on the arrival of a train at the signal, the fireman alights, presses the plunger, and in so doing operates an audible buzzer in the signal-box and causes an indicator to show "train wait-ing." In addition, the block instruments are locked, and the needle turned to the train-on-line position, no matter what indication was there before. The electric horn at the signal denotes to the fireman that these operations have been carried out. The signalman cannot remove the train-on-line indication from his or the rear-box block instrument until he has pegged out. The signalman cannot remove the train-on-line indication from his or the rear-box block instrument until he has pegged his instrument to "train on line" and then pulled over and replaced the home signal to danger. Some companies provide illuminated lamps where such apparatus is installed, but from experience these have not been found necessary.

With the introduction of appliances for the protection of trains detained at signals, it has been found necessary to provide some distinctive indication on home and starting signals at which the carrying out of Rule 55 is dispensed with. A diamond-shaped sign indicates that the train standing at

A diamond-shaped sign indicates that the train standing at the signal is protected by interlocking rotary block, track-

circuit, or treadle arrangement. A D-shaped sign indicates that means are provided for trainmen to protect the train by pressing the plunger of the train-waiting appliance fixed on the ground at the signal at which the train is detained. About 1,200 signals on the Midland Railway are provided with these signs. Other companies are adopting them, and it is hoped that the practice will become universal. Prevention of drivers running past signals at danger.—Some of the most serious accidents in recent years have been brought about by drivers disregarding signals, even in perfectly clear weather. A D-shaped sign indicates circuit, or treadle arrangement.

weather.

weather.

Detonator-placing machines are now used to a very considerable extent to enable the signalman to place detonators on the line to which the signals apply. About 600 of these appliances are in use on the Midland Railway and have been the means of effectively arresting runaway trains. The times, however, call for a more effective and permanent appliance that will be in operation at all times and for all trains.

There are serious obstacles to be overcome, the first of these being the general adoption by all railways of a uniform means of warning drivers that they are approaching the danger zone.

of warning drivers that they are approaching the danger zone. From practical experience it has been found impossible to obtain satisfactory results from any apparatus that relies on

B, Ramp; T, Telegraph wire; S, Switch (operated by lever working signal); B, Battery.
Note.—Battery connected to ramp only when signal is "off."

FIG. 2.-LINE CIRCUIT.

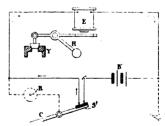

the operation of its parts by impact. It is not considered desirable to give any visual indication to drivers. The author suggests that of all appliances yet introduced, automatic train control and an audible signal go nearest to meeting the before-

mentioned requirements.

mentioned requirements.

Automatic train control and audible signal.—The primary object of this system (figs. 2 and 3) is to give an audible warning on the engine when the train is approaching a distant signal which is at danger, and, in the event of this warning being disregarded by the driver, automatically to apply the brakes so as to ensure the train being pulled up before it reaches the home signal. Another distinctive audible signal is also given on the engine when the distant signal is in the clear position. The value of the latter audible signal is that it facilitates the running of trains when the semaphore signal-cannot be seen during fogs or snowstorms. The audible signals given are the sounding of a siren indicating stop, and the ringing of a bell indicating proceed. The point at which the audible signals are given is usually about 400 yards before the distant signal is reached. distant signal is reached.

This apparatus involves a metal ramp, about 60 ft. in length, fixed in the centre of the 4-ft. way of the raflway, and length, fixed in the centre of the 4-it. way of the raflway, and a contact shoe on the engine, which engages with the ramp to operate the audible signals. The ramp is slightly staggered in order to reduce wear-and-tear on the shoe, and is at the highest point 4 in. about rail-level. The contact shoe is fixed in the centre line of the engine and hangs down to within 2½ in. above rail-level. It is capable of being raised vertically to the extent of 1½ inches whenever a ramp is passed over, which opens a switch attached to the contact shoe. The ramp is

R, Bell; E, Electromagnet controlling brake valve and whistle; Y, Brake alve and whistle; C, Contact Shoe; S², Switch attached to contact Shoe; З², Battery (engine); H, Restoring handle.

NOTE.—Local circuit closed. Electromagnet energized, brake valve and whistle closed.

FIG. 3.-LOCAL ENGINE CIRCUIT.

connected electrically with the signal-box by means of a switch on the lever operating the distant signal, and the signalman can, when the signal is "off," connect it with a battery, so that the ramp is electrically alive; otherwise it is dead with the signal at danger. The switch on the shoe is connected with the electrically-controlled brake valve and the siren in with the electrically-controlled brake valve and the siren in such a way that whenever it is opened air is admitted through the siren and brake valve to the train pipe, thereby sounding the siren and applying the brakes on the train if the ramp is not electrified. Should the ramp be electrified by the signal being "off," when the train passes over it the brake valve is not released, but a bell on the engine rings instead, owing to a current picked up from the electrified ramp, the effect of which is to cut out or render inoperative the switch attached to the shoe, so that although the switch is opened it does not

release the valve admitting air through the siren to the train

release the valve admitting air through the siren to the train pipe. If there is any failure to pick up the current when the ramp is passed over, the effect on the engine is the same as though the ramp was not electrified, the brakes being applied. This apparatus distinguishes distant signals both by day and night, gives distant signals to engine-drivers in the cabs of engines, and dispenses with fog-men at such signals. Another advantage of this system is that ramps may be placed in any position regardless of distance at curves, bridges, tunnels, etc., and can be used on single lines in connection with electric train staff and tablet systems by certain modifications. cations.

The problem of cab-signalling on electrified railways requires much consideration, owing to the fact that the negative rail is placed in the centre of the 4-ft. way, and consequently the ramps would have to be fixed between the negative rail and one of the running rails. There is every reason to suppose that the shoes would have to be duplicated so as to suit the reverse running of trains, both on single and double lines. The possibility of such an apparatus being affected by extraneous currents is another point that would call for special consideration.

consideration.

Railophone.—This system, an invention of Mr. H. von Kramer, as applied for giving an automatic warning in the engine cab of the vicinity and indication of a signal, is undoubtedly designed on right lines, and may be said to mark the latest phase of electrical operation. It is primarily intended for use in connection with distant signals, with the object of giving the desired warning of the position of the signal arm and causing the train brakes to be applied automatically when accession requires should a train overrum a signal. occasion requires should a train overrun a signal.

and causing the train brakes to be applied automatically when occasion requires should a train overrun a signal.

Unlike the automatic train control previously mentioned, this system has no physical connection or contact with either the rolling stock or the permanent way, but is operated entirely on the wireless inductive principle, the transmission of electrical energy being between a fixed circuit on the ground and a circuit placed on the moving train.

An experimental installation has been tested on the Midland Railway, but so far it has not been considered desirable to publish any results. It may, however, be interesting to note that a driver on approaching a distant signal receives three short warnings in quick succession by means of a compressed-air whistle fitted in the engine cab, quite irrespective of whether the signal is at danger or clear. Should the signal indicate danger, the three warning signals are followed by a fourth prolonged signal, and the brakes are automatically applied, but it is so arranged that the fourth signal and the application of the brakes take place only if a driver fails to apply the brakes in the ordinary way after the three warning signals have been received. Should the signal be in the clear position the train is allowed to proceed without interruption, but the driver is aware that he is passing a signal by the three warning signals given on the whistle.

(To be continued.)

(To be continued.)

### ELECTRIC COOKING.

DURING the discussion upon Mr. W. R. Coopen's paper on 'Electric Cooking, mainly from the Consumer's Point of View,' which was abstracted in our issue of March 19th, at the last meeting of the Yorkshire Local Section of the Institution of Electrical Engineers, Mr. Campion said that in regard to heating water at one farthing per unit, on the assumption that the cooking load was supplied at a halfpenny per unit there was a good case for it. He was, however, of the opinion that the central station engineers had taken a very liberal and broad view in cutting down these rates and had done their part; it was now time that the people who were making the apparatus came forward and helped. In Dewsbury the people who had cooking apparatus used about 250 units per month. They had the assessment principle in vogue, and the local authorities stipulated that when a consumer accepted this tariff he must, according to his rateciple in vogue, and the local authorities stipulated that when a consumer accepted this tariff he must, according to his rateable value, install a certain amount of heating or cooking apparatus; in eleven cases out of twelve the consumer installed heating apparatus. The question of outlay was a very big one indeed. In Dewsbury there were some fairly wealthy men, but they would not install apparatus at half the price suggested by Mr. Cooper in his paper. They would not mind hiring it, but they were averse to risking £12 10s. 0d. He endorsed the author's remarks about the earthing of his apparatus. With reference to the flexibles, he believed they had all found—and most of the cable manufacturers were coming to it now—that a steel wire inserted in the flexible gave a good deal more mechanical strength, and he was surprised that it did not come out better on the test. In industrial towns he believed it was being found that the big loads occurred between 10 and 11 in the morning, and they would certainly get a big cooking load when they got a good number of houses upon the mains where mid-day meals were the rule. He knew of a case where a consumer obtained the the rule. He knew of a case where a consumer obtained the following contract with the makers in regard to the maintenance of a cooker which he had purchased:—First year's maintenance free; second year, 8s. 6d. per quarter; third, fourth and fifth years, 17s. 6d. This arrangement was satisfactory to the consumer, because he knew about what the maintenance was going to be.

Mr. Wright said he believed that although lighting and power connections were rising at a satisfactory rate, heating and cooking connections were rising at a more accelerated rate. The question of electric lighting might be taken as settled for all new houses within reach of tenants of a rental value of, say, 7s. or 8s. per week; the houses were now wired as a matter of course, because the owners realised that a house wired for electric light had a better chance of letting. It was different, however, with electric cooking, and it rested with the station engineers and electrical manufacturers cooking plant to supply electric cooking on the same plane as electric lighting. They must not suppose that because electric cooking was progressing the gas cooking was necessarily stationary. Between 1908 and 1912 the number of gas cookers added to the mains of seventeen selected towns in England rose from 811,000 to over 1,000,000, and he had no doubt that since then the total number had risen considerably. The initial cost of electric cooking apparatus very much handicapped the more extensive adoption of that apparatus, and the novelty of electric cookers was reckoned as an experiment. Mr. WRIGHT said he believed that although lighting and capped the more extensive adoption of that apparatus, and the novelty of electric cookers was reckoned as an experiment. From the station engineer's point of view the cooking load was well worth cultivating, as it would give him a better annual load factor and improve his diversity factor at the same time, though it would not, he thought, increase his peak load. The advantages of cleanliness, regulation of temperature, reduction of waste, etc., in electric cookers were bound to appeal strongly in their favour, but the present difficulty was the great difference in first cost of the apparatus as compared with gas or coal cooking. As soon as these became comparable he thought electric cooking would come much more extensively into domestic use and a reduction of the cost of current and maintenance would automatically follow.

Mr. Wallis said he felt that electric cooking was one of the

Mr. Wallis said he felt that electric cooking was one of the coming things, but great difficulties of manufacture had to be overcome. It was by attention to little details that perfection would be attained.

be overcome. It was by attention to little details that perfection would be attained.

Mr. Innes said he believed the ideal place for electric cooking was in flats. He did not think they could get many people to go in for heating water even at one farthing per unit. In his own experience the boiling of water—even tea water and for similar requirements—consumed a great deal of the total energy consumed in the house. The actual cooking was only a small proportion of the total load. Keeping food warm took a good deal of current; and if there was an Ideal boiler installed which served as a hot plate, as mentioned by the author, it did away with a good deal of the cost of current. He totally disagreed with the author's suggestion that the makers or corporations—if they were hiring-out apparatus—might go so far as to repair the apparatus free of cost, because contractors maturally looked to the maintenance to bring some return to them for their expenditure on apparatus. He doubted whether they could get the ordinary cook to keep her eye on the thermometer. He suggested the addition of an indicating lamp on every element and not simply on the main switch, because that was rather misleading. In regard to flexibles, he did not think they got nearly the trouble now that they used to get.

Mr. Lang said that apparently the author, had not differ-

Mr. Lang said that apparently the author had not differentiated between wires insulated with double pure rubber and those insulated with pure rubber and vulcanised rubber. Pure rubber insulation was absolutely of no use at all in damp places or in positions where heat was likely to affect the

rubbers

rubbers.

Mr. Collinson said that as a contractor his difficulty was in selling the apparatus. The cost of an electric cooker was at least three times the cost of a gas cooker, and to hire-out apparatus for a house rented at from £20 to £25 he would have to make a charge of £3 per annum, whereas the Bradford Corporation would hire-out the same cooker at 10s. per annum. The whole trouble seemed to be the high initial cost. Electric cookers were not worth the money the electrical manufacturers were charging for them, but they must agree that the manufacturers had not yet been in a position to manufacturers had not yet been in a position to manufacturers. the manufacturers had not yet been in a position to manufacture them at competitive prices.

Mr. Burnand said there was no doubt that in a good many cases earthing was deficient, and insulation was preferable to

earthing in a kitchen if it could be arranged.

Mr. Moss said that if earthing the portable apparatus was carried out to its uttermost limit, instead of cheapening the cost of the apparatus it would cripple the sales. As a contractor, he maintained that so long as people sent repairs the contractors should have a fair margin of profit on the cost.

contractors should have a fair margin of profit on the cost.

The Chairman (Mr. T. Roles) said that the heating of domestic water could be done successfully by using a large amount of electricity for heating the water as it flowed from the tap. That might be looked upon by central-station engineers as a rather drastic proposal, but he did not think it would affect the pressure on the electric supply mains as much as was generally anticipated, provided fairly large mains were laid. His experience was that screwed steel tubing, if properly carried out, formed a very good earth. There was little doubt that there was a great saving of meat by the use of electricity as compared with either coal or gas ovens.

The Author briefly replied to the points raised in the discussion.

cussion.

^{*}A full description appeared in the ELECTRICAL REVIEW of July 5th and October 11th, 1912.

# FOREIGN AND COLONIAL TARIFFS ON ELECTRICAL GOODS.

PANAMA.—H.M. Minister at Panama has recently drawn attention to the publication in the Gaceta Oficial of a law regulating, amongst other things, ship's manifests, invoices, and fees chargeable by Consular officers. This Act provides that all persons wishing to ship merchandise to a port in Panama open to commerce must present to the Consul of Panama at the port of shipment six copies of an invoice giving the following particulars, viz.: The name of the shipper; the place of origin; the name of the consignee; the name of the ship and port of destination; the mark, numbering class and weight of each package; together with exact details of the goods and their original prices. The charge for certification of the six copies of the invoice is 0.9 per cent. of the total net value of the invoice payable in the currency in which the invoice is made out with a minimum charge of one gold dollar. In addition to Consular fees for certifying invoices, three dollars is charged for certifying each set of bills of lading dealing with invoices of a greater value than 100 dollars, and six dollars for certifying four copies of ship's manifests for every 100 packages, and 1.20 dollars for every additional 100 or fraction thereof. The fee for a ship's manifest covering articles of iron. steel. copper, zinc, wood, tiles and similar goods, is six dollars, however large the amount of shipment. Consular officers can only certify to invoices when they refer to packages with one mark, from one shipper, consigned to one individual or company, and for one place. If invoices are not accurate or do not comply with the requirements, 5 per cent. of the value of the invoice is collected in addition to the duties; when the inaccuracies or omissions, however, are not of a general character, but refer to one or more items, only the fine is imposed on the value of the articles which have not of a general character, but refer to one or more items, only the fine is imposed on the value of the articles which have not been properly declared. The full text of the law and a translation may be seen at the Commercial Intelligence Branch, Board of Trade, 73, Basinghall Street, London, E.C.

NEW ZEALAND.—The New Zealand Customs Authorities have decided that Kelvin composite balances defined as electric testing apparatus may be imported free of duty.

RUSSIA.—With reference to a notice regarding a proposed revision of the Russian tariff which appeared in a recent issue of the Electrical Review, the Board of Trade have now received telegraphic information from H.M. Ambassador at Petrograd to the effect that an Imperial Decree which was promulgated on March 25th and came into force on the same day repeals the Decree of the 16th August, 1914, by which the Russian "conventional" rates of duty (i.e., lower rates the result of Treaties) provided for in the Commercial Treaties between Russia on the one hand and Germany and Austria on the other, were temporarily maintained in force in so far as they were applicable to goods imported from Allied and neutral States. In addition, certain goods are subject to special augmented rates, and the General Tariff rates of duty in certain other goods are increased by 10 per cent. The General Tariff rates for machinery of all kinds falling under Section 167 of the Tariff are not modified. With this exception the effect of the new legislation would appear to be as set out in our previous notice. H.M. Ambassador is forwardset out in our previous notice. H.M. Ambassador is forwarding a translation of the Decree, and as soon as possible after its receipt the Board of Trade propose to issue a Parliamentary Return showing in detail the effect of the amendments now introduced in the Tariff.

SWEDEN.-The Swedish Government have recently prohibited the exportation of the following amongst other goods: Electro-magnetic igniting apparatus for the ignition of motors; lead ore; scrap of pig-iron and malleable iron; unmanufactured tin, also scrap tin; manufactured tin—pipes and parts of pipes, sheets and wire, also rods.

### ELECTRIC POWER ON THE RAND.

IT will be generally admitted that the paper which Mr. J. H. Rider presented to the Institution of Electrical Engineers last week was one of the most interesting and informative essays that have been delivered in recent years. The subject was one of exceptional scope and variety, as may be inferred from the fact that the electric motors in operation have an aggregate of 142,300 H.P.—a colossal system-and the demand for compressed air, which is mainly used for working rock-drills, amounts to no less than 37,900 kw. Plant installed on so large a scale, and so constantly in operation that the load factor of the electrical system is 75 per cent., entails a heavy load of responsibility on the engineer, and affords unique opportunities for the acquisition of experience of the most varied character.

Electrical engineers may therefore be grateful to the author for drawing so freely upon his knowledge as he has done in this paper. While there are many points which invite comment, we wish to direct our readers' attention especially to the subject of main winding gear, which is of constantly increasing importance in connection with British colliery installations. It is not long since engineers in this country were discussing at great length, and with many detailed calculations, the question whether electrical winding could possibly compete with steam winding; that stage, through which so many of the applications of electricity have had to pass -for the British electrical engineer is slow to grasp the possibilities of new openings for his talents—has been safely traversed, and now the question is whether threephase or direct-current motors offer the greater advantages for the purpose.

As in the case of so many other problems, the solution of this one depends upon circumstances, and it is impossible to arrive at a decision applicable to all cases. Where power is derived from the mains of a large power company, the conditions are in favour of the three-phase motor; where a private station of moderate dimensions supplies the power, the use of the Ward-Leonard system of control with a flywheel motor-generator set may be obligatory. Again, the size of the winder exerts an important influence on the decision; for a small winder the objections to the three-phase motor lose much of their force, and the advantages of the It will be remem-Ward-Leonard system are diminished. bered that Mr. C. P. Sparks in his recent paper showed that he employed both types of motor, and the same thing is found on the Rand.

Mr. Rider states that of 69 electric winders, only 9 are of the Ward-Leonard type. Most of the three-phase motors, however, were applied to winders converted from steam drive-47 in number-leaving only 14 wholly new threephase winders, as compared with eight new D.C. winders. Mr. Rider also quotes Mr. Heather as stating that the saving in capital outlay due to using induction motors was probably £50,000. But the working cost must also be taken into consideration, and the author expresses no decided opinion on this point. Moreover, the addition of an eddycurrent brake to the three-phase winder, with the accompanying motor-generator, &c., brings up the capital cost practically to that of the Ward-Leonard system, which is certainly far more handy to control, and probably possesses a much higher degree of safety in operation than the A.C. system. With the eddy-current brake retardation is effected with 45 kw. applied to the magnet system, whereas braking by reverse current on the winding motor requires an input of 1,600 kw., so that the advantage of u ing the brake is obvious. On the other hand, while several eddy-current brakes have been installed, it is quite clear that the majority of the three-phase winders used by the group of

Digitized by Google

[669]

mines are working satisfactorily without their aid. There is also a significant paragraph in which the author points out that three-phase motors running at comparatively high speeds and driving through gearing can be advantageou ly employed, whereas with the Ward-Leonard system the motor is preferably direct-coupled.

So impartially does Mr. Rider weigh the pros and cons, that it is difficult to detect in his paper any decided leaning towards either system; but, on the whole, while he says that each case must be considered on its merits, we think that where the arguments on either side appeared to be of equal weight, he would prefer to install the Ward-Leonard

control.

Not the least interesting and valuable feature of the paper is the section dealing with the "troubles" that the author has met with, due mainly to faults in design and manufacture. These call for the earnest attention of our manufacturing firms, with a view to their avoidance in the future. Some of the examples cited of bad workmanship and material were absolutely disgraceful, and there is little consolation to be derived from Mr. Rider's statement, in his reply to the discussion, that they were fairly equally divided between British, American and German products. For faults in design, the author finds some excuse in the limited experience of the designer with regard to the work a machine may have to do; but this is really an explanation rather than an excuse. We fear that, only too often, designs for new types of machines are entrusted to men who have seen little or nothing of the processes for which the machines are required, and who cannot make good their deficiencies by a hurried search through the text-books available; though it may be flattering to the D.O. to be credited with the ability to design any mortal thing that may be called for, from its inner consciousness, sooner or later disaster is bound to come. It would be well worth while to dispatch a capable designer to the Rand, as well as to other important industrial centres, to find out exactly what is required and what unsuspected conditions exist that must be provided against.

Such pipers as that of Mr. Rider afford immense assistance to those who have to supply the plant, and we trust that Bitish manufacturers will profit by the information now at their disposal, so that full advantage may be taken of the opportunities that will be open to them after the war. An abstract of the paper will appear in our later issues.

THE more we read concerning the The Russian Russian Electric Lighting Co. of 1886, Government and of Petrograd, the expropriation of which is proposed by the Russian Government, Interests in Supply Works. the more does it appear that the latter are in possession of better information than is revealed by the German and German-Swiss newspapers of the actual situation of affairs, or the liquidation of the company would not be contemplated even at the present time. The company was formed in 1886 as a Russian company on the basis of statutes which were sanctioned by the Russ an Government. Lighting conc-ssions were obtained from the City Councils of Petrograd and Moscow under definite agreements which provide, among other matters, that the former city possesses the right of acquiring the local undertaking for the first time in 1918, according to definite terms specified in the concession, whilst Moscow is similarly situated in regard to the purchase of the city undertaking in 1920. An extens on of the company's scope was subsequently made to Lodz and other Russian towns, but the chief business was concentrated in the capital and in Moscow. Unfavourable early years, the loss of capital, the reorganisation undertaken in the nineties of the past century with the assistance of German and Swiss capital, the impossibility, as is said, of procuring further Russian capital, and the aid, sought for and obtained, of further German and Swiss capital-all these causes contributed towards the disposal of the greatest portion of the shares in Germany and Switzerland, a small portion only being in Russian and French possession. Indee i, it is stated that it was impossible to awaken

interest in the shares to a greater extent in Petro-

grad, notwithstanding the efforts put forth in this direction. Gradually, however, the shares are declared to have been increasingly transferred to Switzerland; ordinary shares for 41,000,000 roubles and preference shares for 9,000,000

roubles were recently in Swiss ownership.

Now the Government must be in the position to know exactly from the company's records when those transfers took place, and to what persons or banks or other institutions in Switzerland the shares were diverted, and the question or origin of partly German banks or other partly German financial institutions in Switzerland, and their relations with German banks or other financial institutions or electrical firms in Germany, should probably also be known. If the Russian Government, however, are not in possession of details which prove that the company is merely a German undertaking under a Russian title, it is difficult to understand the drastic Bill which the Swiss Neue Zurcher Zeilung states, as a result of inquiries, the Government has prepared for the liquidation of the company. The Bill provides that the Government will appoint a commission to ascertain the value of the undertaking in full operation, and to consult the cities and third persons. After the price has been determined by the five representatives of the Government and the two cities, the cities of Petrograd and Moscow may acquire the undertakings in question during one month, at the fixed price. If the cities refuse, the right will pass to the Government, and if the State also declines to exercise the right, a public auction is to take place. During the period of the liquidation the management will be entrusted to a second commission of seven members, of whom three will be appointed by the Government, two by the two cities, and two from the existing board of directors.

The Russian Government would scarcely proceed with a Bill of this nature unless certain that the undertaking was almost entirely German. Russia has been so greatly indebted to foreign capital, and will be so to a still greater extent after the war, for the development of her enormous resources, that it is unlikely that steps likely to shake the confidence of foreign investors would be taken without excellent reason. If Swiss ownership has really preponderated in the company for several years past, the holders are assured of the support of the Federal Government in protecting their financial interests.

THE rubber market has had a pretty Rubber. firm appearance lately, and there have been times when the trade demand showed signs of developing upon a fairly satisfactory scale, while prices showed some improvement. The moderate quantities actually available were recently absorbed more freely than had been the case for some little time, and there seemed to be a little apprehension among consumers less the filling of the extra requirements usually met with at this, the most active period of the year, in the manufacturing trades, should, combined with belated landings, lead to a temporary scarcity. There is a possibility, too, of shipments from the East being delayed owing to freight difficulties. Prospects as to consumption in Europe and America are quite encouraging, because war requirements are licking up such enormous quantities of material that the closing of the German market is hardly felt. Shipments to America should continue on a pretty good scale over the spring, provided matters proceed normally as regard shipments. The deliveries of plantation grades have been better than for some weeks past. The total outgoings in London during last month were 6,363 tons, or nearly 400 tons in excess of the arrivals. A very large portion has been absorbed by clearances for America. When allowance is made, however, for the increased stock of Para grades in Liverpool there seems little alteration in the total stocks here, which amounted on April 1st, to 8.980 tons against 6.609 tons last year, and 5,967 tons in 1913. It is generally acknowledged, however, that the London stocks as indicated above are misleading, because they include considerable quantities which have been actually sold, but have not been delivered, owing to transport and other difficulties. The enormously large transport and other difficulties. contracts now in course of execution by manufacturers point

to the continuance of an active consumption, and holders appear to be quite hopeful as to the course of the market during the next few months. The Brazilian export trade returns have been officially returned for 1914 as 32,526 tons against 35,304 tons in 1913.

According to a telegram from the Government to the Malay States Information Agency, the reports of rubber from the Federated States for the month of March amounted to 3,418 tons, compared with 3,411 tons last month, and 2,418 tons in the corresponding month last year. Appended are the comparative statistics:—

	1918.		1914.	1915.

Those who Fall by the Way.

THE Electrical Trades Benevolent Institution has been in existence eight years, and its accumulated funds amount to less than £8,000—a total still unworthy of

the electrical industry and utterly inadequate to meet its needs. "He that has no charity deserves no mercy," and charity certainly cannot be expected to come to us from outside if we of the electrical industry have not a Further, it cannot be expected that faculty for it within. employers and shareholders should make systematic contribution to electrical benevolence unless those who one day may wish to claim that benevolence, support it when they are on the upper spokes of Fortune's wheel. It is true that the income of the Benevolent Institution was nearly three times as great last year as in 1913, but very special causes contributed to that end, and, with war in progress, and every probability of increased demands for assistance in the near future, wholesale additions must be made to the sources of On the basis of the past two or three years' revenue. figures, it would be 60 years before one could enjoy the prospect of being accommodated in the Institution's almshouses, and at least two generations before the child of any worker in the electrical industry could be offered the shelter of an orphanage. Such a state of affairs is neither creditable to the electrical industry nor fair to the Benevolent Institution. The funds collected are administered faithfully and well, but they are totally inadequate. Expenses cannot be reduced, for they are already low for the range and amount of work done. It is income which must be increased, and as capital may not be spent, funds must be raised to provide sufficient dividends and interest to alleviate every genuine case of distress in that large and ever-increasing middle-class stratum of the electrical industry which has no other organised benevolence to rest upon. The primary object of the Institution is to render financial and other assistance such as will lead to permanent benefit, and in the past about 75 per cent. of the recipients of grants have been assisted to permanent employ-Later, as available funds increase, the activities of the Institution can be extended, but the first essential is to provide an ample and secured income.

If each of the five or six thousand electrical firms in the country subscribed five guineas, or even one guinea, per annum, and if each of the tens of thousands of employes who stand to benefit by the aims of the Institution contributed 10s. or even 5s. per annum, there would rapidly accumulate funds permitting relief to be given to everyone in distress in the electrical industry. A collection after every electrical staff donner or public banquet would amount to a respectable total in the course of a year. There are many other pressing claims, but the electrical industry can and ought to establish a really adequate benevolent tund. As Mr. Garcke said on Monday in presenting the annual report of the Institution, the problem is not what is the right thing for each one of us to do, but what steps can be taken to awaken us to our duty and persuade us to perform it. "All mankind's concern is charity," and we issue a sincere and urgent appeal to the large number of persons engaged in the electrical industry who have not yet identified themselves with the excellent work and ambitions of the Electrical Trades Benevolent Institution.

THE BECK SEARCHLIGHT PROJECTOR.

In the course of a discussion before the Society of Illuminating Engineers recently, some particulars were given of a new searchlight are invented by Mr. Heinrich Beck, and were published in our report of the meeting. Further information on this subject was given in a paper read before the American Institute of Electrical Engineers in February last, by Mr. C. S. McDowell, the gist of which is given below.

The author states that the lamp mechanism of a search-light should keep the crater of the positive carbon at the focus of the mirror, should keep the arc length that which is desired, should carry the current of the carbons, should contain mechanism for rotating at least the positive carbon, should be sufficiently rigid to keep the carbons in proper alignment, and should require little care and adjustment.

An illustration of the Beck lamp mechanism is shown in fig. 1. Both carbons are rotated for the purpose of keeping their surfaces bathed in the inert gas and to keep the arc

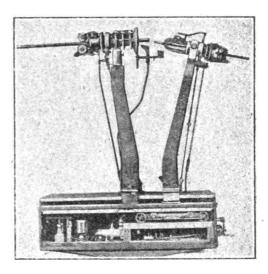

FIG. 1.—BEOK SEARCHLIGHT LAMP.

central, and thus promote evenness of burning. The positive holder is fixed, the carbon being fed through it at such a rate that the crater is always maintained at the focus of the mirror; the rate of feed is controlled automatically, a small mirror being placed in the drum, which, when the carbon feeds too slowly, reflects a small beam on a thermocouple, and clo-es a relay circuit, which, by means of a solenoid, quickens the feed. When the carbon is back in focus, the small beam of light is off the thermocouple and the feed is slowed down. In addition, the feed may be controlled by hand. The negative carbon is fed through the negative holder in a similar manner, except that the The negative holder is also fixed, control is by hand. except when striking the arc, when it is moved up by a striking motor.

During tests recently conducted on searchlights, the Beck lamp mechanism functioned very satisfactorily; variation of the crater of the positive carbon from the focus was about 1 mm. (hardly noticeable), and the arc length was kept practically constant. No trouble in maintaining the arc was experienced while rotating both carbons, the crater of the positive carbon remained even, and there was no noticeable hissing or jumping of the arc.

The desired searchlight arc should excel in the following particulars:—

- 1. Small positive carbons with high current densities and thus high crater temperature throughout the crater area, which gives high intrinsic brilliancy.
  - 2. Small negative carbons.
- 3. Long arc length, that is, distance between positive crater and negative point.
- 4. Uniform mixture of carbon so as to help the evenness of burning.

The Beck searchlight may be considered as being especially

designed to meet the above requirements, and therein lies its marked superiority over the searchlights now in use.

In a searchlight the angle of dispersion is directly dependent on the diameter of the source of illumination, provided the focal length is constant, and if the diameter of the source can be decreased one-half while the candle-power remains constant, the intensity of light on the target will be quadrupled. Actually in the Beck searchlight, the positive carbon is reduced one half, and at the same time the candle-power is increased, so that greater efficiencies are obtained.

To decrease the angle of shadow it is necessary to increase the arc length or decrease the diameter of the negative carbon. The arc length is restricted to the stability point of burning. Whilst complying with this requirement, the arc length of the Beck lamp is maintained constant at about  $\frac{7}{6}$  in as compared with about  $\frac{7}{6}$  in obtained at 60 volts

in the standard 36-in. lamp.

Carbon is the most refractory of all known materials, boiling at about 4.000° C., but it unfortunately commences to evaporate at a much lower temperature (about 1,800° C.), so that in an ordinary arc very little of the total area of the end of the positive carbon is at the melting temperature, a small wandering spot being the real efficient part of the carbon, and the rest of the end of the carbon is consumed at a much lower temperature, giving off less intense rays and a longer wave length. This may be readily seen in a comparison of the Beck and ordinary arcs by the colour of the arc.

In the Beck are the ends of the positive and negative carbons are enveloped in hydrocarbon vapour, which prevents the consumption of the carbons at a lower temperature, by keeping oxygen from them; in addition it cools the outer shell of the carbons, the gas being at a temperature of about 1,000° C., and thus concentrates the current in the centre of Thus a current density greater than 0.75 ampere per sq. mm. is obtained, and the whole crater of the positive carbon reaches a very high temperature. current is brought to both carbons near the ends by roller contacts, so that the only part having this high current density is the part protected by the indifferent gas. The positive carbon is cored with a rare earth having a melting point of about 3,500° C. The positive develops a deep crater, about 12 mm. deep, filled with incandescent gas. The sides of this crater reflect the light radiation to the focus of the crater, and, in addition, the light from the negative is reflected, so it is believed that nearly true blackbody radiation is obtained; and by adjusting the focus of the crater to the focal point of the mirror the high peak in the luminosity curve of the beam is thus produced.

FIGS. 2 AND 3.—BECK SEARCHLIGHT ARCS.

The area of the Beck positive carbon is 201 sq. mm.; the area of the ordinary 36-in. searchlight positive carbon is 805 sq. mm. In the Beck light the maximum intrinsic brilliancy is greater than 438 c.p. per sq. mm. The intrinsic brilliancy of an ordinary carbon arc varies from 120 c.p. per sq. mm. to 160 c.p. per sq. mm.

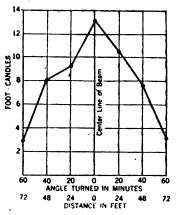

In addition to the black body radiation obtained from the crater, there is evidently a large amount of light radiated from the incandescent gas in the crater, of a selective nature. It would probably at first be thought that this gas would follow Kirchhoff's laws and absorb the lines which it naturally radiated, giving the Fraunhofer lines seen in the sun's

spectrum; but in this case the incandescent gas higher temperature than the crater, and the spectrum positive lines apparently superimposed on the regular te perature radiation.

The temperature of the incandescent gas within the positive crater is estimated to be between 5,000° and 5,500° C. Two views of the Beck carbons burning with normal current densities are shown in the illustrations,

figs. 2 and 3.

It is very hard to compare two searchlights by the eye, but during a test both searchlights were lighted (the Beck and the U.S. Navy 36-in.), and first one and then the other was turned on the same object, with the result that objects not distinguishable, except in a hazy way, with the Navy 36-in. were plainly outlined by the Beck light. It is apparent to the eye that the Beck light is more of a bluish-white light than the standard; the ordinary searchlight beam looks yellow in comparison. The aggregate quantity of blue and violet rays in the Beck beam is about 23 per cent. At low intensities of illumination the maximum sensation to the eye for the same strengths of illumination shifts towards the blue end of the spectrum, while at higher intensities of illumination the maximum sensation for the same strengths is towards the yellow part of the spectrum. This shifting of the relative sensations for different intensities of illumination

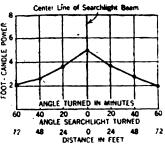

FIG. 4.—FOOT CANDLE-POWER-DISTANCE CURVE OF THE BECK 44-IN. SEARCHLIGHT TAKEN AT A DISTANCE OF 2.850 FT. LAMP BURNING NORMALLY.

FIG. 5.—FOOT-CANDLE-POWER-DISTANCE CURVE OF THE NAVY STANDARD 60 IN. SEARCHLIGHT TAKEN AT A DISTANCE OF 2,850 FT. — LAMP BURNING UNDER NORMAL CONDITIONS.

is the well-known phenomenon called the Purkinje effect. It is thus seen that the Beck light is particularly good for picking up distant objects where the illuminative intensity would be small.

It is also a well-known fact that a coloured body reflects the colours from the rays falling on it which the body itself contains, and absorbs the rays which it does not contain; the Beck light being strong in the short waves of light would thus be particularly effective in picking up objects of a bluish colour, such as the various classes of ships painted bluish grey.

Comparative night illumination tests were conducted between standard 36-in. and 60-in. searchlights and the 44-in. Beck searchlight. The beam given by the latter was a more concentrated beam than that obtained from either of the standard lamps, and the colour of the Beck beam was

whiter.

With the carbons burning in a normal condition and placed in the proper focal centres of their respective mirrors, foot-candle-power readings at intervals of 24 ft. were taken across the beam at a distance of 2,850 ft. from the searchlights. Figs. 4 and 5 show the illumination across the beam of the Beck searchlight compared with that of the 60-in. standard searchlight. From these curves it can be seen that the maximum illumination obtained from the Beck light is approximately two and a-half times as great as that obtained from the standard 60-in. projector. In the Beck searchlight beam the illumination is very high at the centre and falls off very rapidly at the edge of the beam.

The maximum candle-power obtained with the present US. Navy standard carbons is 45,000 c.p., as against

88,000 c.p. obtained with the Beck lamp.

From the Electrical World we reproduce fig. 6, showing the complete projector, with the spirit tank mounted on the side of the barrel. The vapour is generated from methylated spirit in a cylindrical chamber filled with wire gauze, and heated by a small electric resistance heater, the spirit being admitted at a uniform rate into the vaporiser, where it is volatilised on the hot metal parts, escaping in the form of gas through nozzles under the electrodes. The spirit is fed automatically, when the arc is struck, by an electromagnetically-controlled valve.

The diameter of the negative electrode for 150 amperes is only 11 mm., and, owing to the protective effect of the vapour, the rate of consumption is only 50 to 60 mm. per

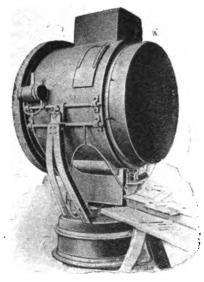

FIG. 6.—EXTERIOR OF PROJECTOR.

rotaries, arranged for either lighting or traction supply. The two rotary converters are of 500 kw. capacity each, of the six-phase type running at 750 B.P.M., and were also supplied by the British Westinghouse Co.

Westinghouse Co.

They are 8-pole horizintally divided machines, each with an alternating-current booster and squirrel-cage starting motor mounted on the same shaft, and supply either lighting or traction voltages; the main transformers are each of 550 K.V.A. capacity, of the oil-insulated self-cooling type.

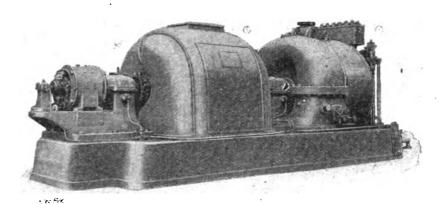

The boosters allow of complete and independent control of the power factor on the A.C. side and of the D.C. voltage

The new plant in the boiler house consists of two Stirling water-tube boilers fitted with superheaters and underfeed mechanical stokers.

One boiler has a heating surface of 5,157 sq. ft. and a grate area of 91 sq. ft., and will evaporate 26 000 lb. of water per hour; in the case of the other boiler with 5.719 sq. ft. heating surface, and 93 sq. ft. grate area, the evaporation is 29.000 lb.

The superheaters, made by Superheater Unite, Ltd., consists of four distinct units of 88 tubes giving a total heating surface of 580 sq. ft.

The stokers were supplied by the Underfeed Stoker Co., Ltd., and are of the push-plate typs.

B.T.H.-CUBTIS TURBO GENERATOR, AS INSTALLED AT SWANSEA.

hour; for the positive electrode a rate of 200-250 mm. per hour is allowed. The positive electrode can be renewed in a hot projector in a few seconds, and whereas the ordinary projector arc burns unsteadily until the carbons have settled down to shape, the Beck arc is ready for work within a few seconds.

The positive electrode is 16 mm. in diameter, as compared with the ordinary carbons, 38 mm. in diameter, for the same current (150 amperes). The positive is not reduced to a point, but maintains its full diameter up to the crater.

The Uplands sub-station plant consists of two 500-kw. rotary converters, together with the necessary transformers and switch-

The cost of this extension, for the particulars of which we are indebted to Mr. J. W. Barr, the borough electrical engineer, has been some £40,000.

# SWANSEA ELECTRICITY EXTENSIONS.

WE referred in a recent issue to the three-phase plant which has been brought into use by the Swansea Corporation electricity

This consists of two 1,875-K.V.A. turbo-alternators, with rotary converters and the necessary H.T. switchgear at the power station, where also n.w boiler plant has been installed; H.T. trunk feeders, and sub-stations, only one of which, at Uplands, is ready for running at the moment.

running at the moment.

The turbine plant is of the horizontal Curtis type supplied by the British Thomson-Houston Cc., giving its rated output at 3,000 BPM. and supplying energy at 6,600 volts and 50 periods. Overloads of 25 per cent. for two hours and 50 per cent. for 10 minutes are provided for, with normal steam pressure (150 lb.) and 85 per cent. vacuum. Centrifugal and emergency governors are fitted and the governing can be electrically adjusted from the switch gallery. The air for ventilating the turbo-alternators is supplied through ducts from dry air filters fixed outside the building. building.

The turbines exhaust into Cole, Marchant & Morley condensers, in connection with which are Edwards air pumps and circulating pumps, the pumps for each condenser being driven by a single motor.

Each condenser is designed to maintain a 28-in. vacuum when dealing with 27,000 lb. of steam per hour, with cooling water at 65° F. and a 30-in. barometer.

The three-phase H.T. switchgear was supplied by the British Westinghouse Co., and is of the remote controlled type; the L.T. control switches and instruments are mounted on a bench board, provided with red and green lamp indicators.

provided with red and green samp indicators.

The bus-bars oil switches, &c., are enclosed in moulded stone cubicles. This switchgear controls the two turbo-alternators, also two rotary converters and four three-core '1 sq. in, outgoing feeders. Two direct-current panels have also been supplied for the

Letters received by us after 5 PM. ON TUESDAY cannot appear until the following week. Correspondents should forward their communications at the earliest possible moment. No letter can be published unless we have the writer's name and address in our possession.

### The Capturing of German Trade.

Now that the time for the electrical industry is here, in all seriousness—and has been for some time past, as a matter of fact—to arouse itself and concentrate on the prime factors which will enable it to capture and hold that large volume of trade which has been hitherto secured by our present enemies, the Germans, not only in these islands, but in all parts of our Empire, and also in the markets of our Allies, does it not behave the industry at once to set about what is one of the most essential primary movements to ensure this end?

It seems to me that the industry en bloc should immediately take those steps which will not only ensure the inception, but also the continuity, of the propaganda campaign, v.z., by the preparation and publication of catalogues ir, say, French, Russian, Spanish, and even in Japanese and Chinese, and, in fact, in the languages of all those countries with which we have every hope our mutual of all those countries with which we have every hope our mutual interests will be linked up and advanced in the future. We might leave the German language alone altogether, as, in any case, for some considerable time after peace is declared, it is highly improbable that we shall do much business with the Germans, at any rate, as sellers; as their customers we have had enough of them in the past, and should do all in our power not to give them the benefit of good British gold any more than we can possibly help, until such time as they can give us some evidence that they can to some degree be trusted. Therefore, for the time, blot their language eut of our trade literature. The languagesmentioned at the commencement of this letter will suffice for all international trading. international trading.

Perhaps one or two of the bigger and more important firms may be able to afford their own publicity and translation staffs, and will individually take up the running on the above lines, but there must be a large number of firms with not overflowing financial resources who would find it difficult, if not actually impossible, to employ their own translators capable of efficiently producing well-finished technical catalogues and propaganda.

Might I suzgest that the present moment appears to be a particularly opportune one to institute a central organisation on behalf of the electrical industry (this might be undertaken under the arspices of the I.E.E. or the B.E.A.M.A.), where catalogue and propaganda matter might be efficiently dealt with by a competent body of linguists who have engineering training and capabilities. At this time, when there must be resident in this country bilities. At this time, when there must be resident in this country a goodly number of electrical and mechanical engineers of french, a goodly number of electrical and mechanical engineers of French, Russian, and Belgian nationality, too old to join the fighting forces, or perhaps already incapacitated from further fighting, who would be only too glad to avail themselves of an opportunity to do some-thing not only remunerative but also patriotic on behalf of their own particular country's future interests, such a central organisa-tion could be established almost at once, I feel sure, given the necessary initiatory spirit.

necessary initiatory spirit.

There would be nothing to prevent the electrical firms from sending their copy to this institution, and paying for translations at a scheduled rate to be decided upon by the promoters and executive of the organisation. The particular style of cataloguing and printing could still be dealt with as at present by the firm's own printer or publisher. The writer has epoken to several representatives of publishing houses, and feels sure that there would be no hesitation in these firms quickly adapting themselves to the demand by the provision of the necessary type of printing—for instance, Bussian type is somewhat outside the ordinary, likewise Jap ness and Chinese—a, once having started, the trade for them in this direction would undoubtedly be a remunerative one.

them in this direction would undoubtedly be a remunerative one.

Again, surely we have now had enough of the suspicion of each other among our home manufacturers. No doubt the German element in our midst was greatly responsible for this, but with that element eliminated, and the experiences which the war has taught us, undoubtedly there will be a return to the good old British axiom, so prevalent in the days of our trading forefathers, of "Let us trust each other."

Euch firm's specialities are nowadays so defined, and it is always has been—such an easy thing for any firm to get hold of its rival's catalogue, that there should no longer be any distrust or sitation in deciding upon some course which will work out, not only effectively but comparatively economically, in the common cause of the industry.

The writer hopes that the idea put forward may receive the serious consideration of the electrical trade, but the principal point is—not to adopt the laissez faire policy, but that of "Do it now!"

The principle might be extended to the establishment of a central school of languages for the teaching and training lineventually of commercial and engineering travellers, who will eventually be required to follow up the propaganda in foreign countries—i.e., if we have learned anything or are likely to learn anything as the outcome of this terrible world upheaval, and we are to ensure that never again will B:itain be caught napping.

The average monolinguistic Englishman has for many years be almost the laughing-stock of his German rival, because he could not speak several languages, but the writer fancies this will be another instance where "those laugh best who laugh last," and, as in the matter of figuting, the Englishman will prove himself also not wanting in the matter of linguistic achievements, when he not wanting in the matter of hinguistic congnises the necessity of grappling with the issue.

Suggestive.

London, April 19th, 1915.

### Electric Road Rollers.

The letter re " Electric R al Rollers" from your correspondent, Mr. Tiplias, is particularly interesting, as the next issue of the Electric Vehicle will deal largely with electric battery traction for municipal purposes, and the question of electric road rollers will be dealt with in an Editorial.

I have sent the draft to a well-known maker in order that any possible "bloomers" may be eliminated, as I am not an expert in this type of machine, but, from a common-sense point of view, it does seem to me that electricity applied to road rollers ought to change for the better the whole aspect of this branch of municipal work. The present steam roller is an unmitigated nuisance on a mount of its noise, smoke and dirt.

The necessary weight can easily be obtained in the form of the battery, and there is no question whatever that the cost of upkeep (repairs, maintenance and power), must be considerably less than with the steam or petrol-driven machine. I believe if one or two enterprising makers took the matter up—it would result in advantage to them, and to the central-station engineer, who would tap a source of revenue.

The journal does not go to press until the end of May, and in the meantime any information on the subject that your readers can send me will be very welcome and help along the movement.

A. Hugh Seabrook. Hon. Editor, The Electric Vehicle.

London, W., April 17th, 1915.

Ball-Bearing Extensions .- THE HOFFMANN MANU-PACTURING Co., LTD., of Chelmsford, are still further considerably extending their already large works. Their ball-bearing hanger extending their already large works. Their ball-bearing hanger for line shafting has been in great demand during the past year, the total supplied being sufficient to carry 42,000 ft. of line shafting at normal pitch.

# LEGAL.

### TAUNTON r. HARKNESS BROS.

THE Electric Appliances Co. were on April 15th defendants in an action heard in the King's Bench D.vision, before Mr. Justice Low and a common jury, in which Mr. Thorn Lionel Taunton, a travellessin electrical fittings, &5., residing at Ealing, claimed commission and compensation for wrongful dismissal.

According to the opening statement of MB. MAYER, K.C., who appeared for the plaint ff, an agreement was entered into verbally between plaintiff and Messrs. Harkness Bros, for him to travel in vacuum cleaners on commission and £1 a week for travelling vacuum cleaners on commission and all a week for traveling expenses. The engagement dated from May, 1911, and the plaintiff's operations were confined to London. Subsequently Mersrs. Harkness's business was turned into a company, and plaintiff continued his duties under the original agreement. In 1913 he was asked to give demonstrations with the vacuum cleaner upon the understanding that his commission should continue the subsequence of the subsequence of the subsequence of the subsequence of the subsequence of the subsequence of the subsequence of the subsequence of the subsequence of the subsequence of the subsequence of the subsequence of the subsequence of the subsequence of the subsequence of the subsequence of the subsequence of the subsequence of the subsequence of the subsequence of the subsequence of the subsequence of the subsequence of the subsequence of the subsequence of the subsequence of the subsequence of the subsequence of the subsequence of the subsequence of the subsequence of the subsequence of the subsequence of the subsequence of the subsequence of the subsequence of the subsequence of the subsequence of the subsequence of the subsequence of the subsequence of the subsequence of the subsequence of the subsequence of the subsequence of the subsequence of the subsequence of the subsequence of the subsequence of the subsequence of the subsequence of the subsequence of the subsequence of the subsequence of the subsequence of the subsequence of the subsequence of the subsequence of the subsequence of the subsequence of the subsequence of the subsequence of the subsequence of the subsequence of the subsequence of the subsequence of the subsequence of the subsequence of the subsequence of the subsequence of the subsequence of the subsequence of the subsequence of the subsequence of the subsequence of the subsequence of the subsequence of the subsequence of the subsequence of the subsequence of the subsequence of the subsequence of the subsequence of the subsequence of the subsequence of the subse tinue while he was so engaged, and that his interests, which would be looked after by others meanwhile, would not be affected. The defendants then asked him to part with half of his commission to those who looked after his business, but this he declined to do. Subsequently differences arose over the plaintiff's letters from customers duently differences arose over the plaintiff a letters from customers being opened at the office and acted upon by other travellers, and plaintiff wrote stating that letters from his clients addressed to him personally "must" remain unopened and left for him to deal with personally. To this communication the defendants took exception, characterising it as impertinent, and demanding a written apology within 24 hours, failing which he would be given a week's notice. The plaintiff told the defendants' directors that he was sorry they should have regarded the word 'must" as offensive, and assured them that it was not so intended. They, nevertheless, gave him week's notice, and he had to leave,

The PLAINTIFF was called, and in the course of his cross-examination his LOEDSHIP said there was no justification for saying that he (plaintiff) had been guilty of misconduct, as was alleged as the reason for his dismissal at a week's notice instead of six months, claimed to be the custom where travellers were paid by commission only. It was absurd to say that the word "must," as used by the plaintiff, was offensive, and his neglect to send a written apology could not be construed into a refusal to obey reasonable orders. It was clear that there had been no misconduct, and it was a serious matter to make such a charge against a man where there was no foundation for it. He suggested that the parties, under the circumstances, might come to some arrangement.

After consultation between counsel, it was agreed that judgment should be entered for the plaintiff for an agreed amount, with costs, and that the £26 3 . 7d. paid into Court by the defendants should be paid out to the plaintiff's solicitors.

Judgment was accordingly entered for plaintiff for an agreed amount, endorsed on counsel's briefs, with costs.

PRIZE COURT.—SEIZURE OF ELECTRIC FARS.

SIR SAMUEL EVANS, presiding over the Prize Court, again had before him a few days ago the case in which the Crown asked for condemnation of five cases of electric fans seized on board the P. & O. steamship *Poona* in London on Ostober 17th. The goods were claimed by I-aria, Ltd., of 208, Tower Bridge Road, a company duly incorporated in England on May 30th, 1912. The matter was adjourned from last term for further evidence to be produced by the claimants.

MR. A W. ELKIN, on their behalf, said he now produced certain MR. A W. ELRIK, on their bottain, said needow produced certain documents which were asked for on the last occasion. The first was a duplicate of the agreement made between claimants and Messrs. Lascelles, Parrington & Brasche, of Melbourne, appointing the latter their agents in Australia. The original was in Melbourne. That proved beyond doubt, he submitted, that Messrs. Lascelles, Parrington & Brasche were claimants' agents. The next documents consisted of a bundle of reports from Mr. Charles Brandt claimants' traveller in Australia and a number of com-Brandt, claimants' traveller in Australia, and a number of ocmmission notes batween claimants and their agents.

The PRESIDENT said it rather looked from these documents as if

the goods belonged to the claimant company, and that Mesars. Lascelles, Parrington & Brasche were only the agents for sale, and Mr. Brandt was the traveller. He would like to see the share

MR J. B ASPINALL (for the Crown) said he had a list of the shareholders, dated July 18th, 1914. There seemed to be seven shareholders, all German. He gathered that his Lordship was satisfied that these goods were the property of the Isaria Co.

The PRESIDENT said he would like to have some further

evidence from Mr. Moreton, the manager of the company.

ME. FRANK MORETON, recalled, stated that the document appointing him manager was signed by Mr. Ludwig Schoenmann, the engineer and secretary, and by Mr. Carl Seifer, the commercial manager, on August 3rd.

The PRESIDENT: What became of them after they appointed

WITNESS: They left the country on the night of August 3rd, to the best of my knowledge. I think they went to Germany rid

Have you had any communication with any of the directors since you were appointed?—No; I account to no one but the Board of Trade Supervisor.

Replying to Mr. Elkin, Witness said that the Board of Trade

were quite satisfied with his mode of carrying on the business, and they countersigned all the cheques drawn by him on the company's amount.

Gross-examined by MR. ASPINALL, WITNESS said he did not know what authority the two gentlemen who appointed him manager had so to do. He assumed they had authority from the

MR. ELKIN submitted that Mr. Morton was properly appointed, and that having regard to the fact that the clampants were a duly incorporated company in this country they were entitled to the release of these goods, on the authority of the decision of the Court of Appeal, in the case of the Continental Tyre and Rubber Co. v.

Tilling.
The President: Supposing this company constituted as it is wanted to buy ships, could it own them?

MR. ELKIN said that had not been decided

The Persident remarked that it would be very odd if the company was the owner of the ship and also the cargo, and was entitled to the cargo and not to the ship.

Mr. Elkin said he relied very strongly on the decision of the

ir.

11.

Court of Appeal. The PRESIDENT said he was willing to pay all deference to that decision, but it did not bind him in that Court. He might after careful consideration come to the conclusion that he might be able to agree with Lord Justice Buckley's dissenting judgment.

Vitimately, his Lordship reserved judgment.

### TRADING WITH THE ENEMY.

In the City of London Court, on April 19th, a considered judgment was delivered by Judge Atherley-Jones, K.C., in a case of much trade interest and importance, in which Brune Ullmann, successor to Bechmann & Ullmann, 21, Moor Lane, E.C., sued Mr. S. Nyman, 30, Westbourne Grove, Bayswater, for £11 5s. for trade goods supplied. The defence was that the plaintiff could not recover because of the Trading with the Enemy Act, although the defendant was quite prepared to pay if so ordered. Plaintiff, it seemed, was a German by birth, and was naturalised in 1899. In 1901 he said he went into partner-hip with Bechmann, a German. Bechmann died and the business passed to Ullmann. The goods sued for were ordered and delivered in March of last year. Plaintiff ranked as a British subject and was entitled to all the assets of the concern including the debt due from the defendant. There could be no question there of trading with the enemy. Pisintiff had o m-municated with the Board of Trade, the Treasury, and the Con-troller of Companies, and they had no objection to him recovering. Of course he would not part with the money or send it to Germany. The business here was a London branch. The headquarters were in Refurth. The business here was a distinct entity. The goods in Refurth. The business here was a distinct entity. The goods supplied to the defendant were invoiced from London and Germany. Defendant said unfortunately his business was with foreign houses, and during the last two months there had been awful trouble through people paying money. He had already got into trouble with the authorities for paying in another case.

JUDGE ATHERLEY JONES, K.C., said that as the point raised was a novel one and had never been before any Court, and as it was

was a novel one and had never been before any Court, and as it was of great importance to every trader in this country, he had taken time to consider his decision. He had come to the conclusion that plaintiff could not recover as he was satisfied that the buriness of Ulimann & Bechmann was a German house. As for the correspondence with the Board of Trade, &c., it was immaterial, as Courts of Law did not found their judgments on the opinions of Government officials. Plaintiff's business in London was only an agency. Judgment for the defendant with costs, but he gave leave to the plaintiff to appeal, as he thought it quite likely that the Divisional Court might take another view. I: was certainly a very important case.

very important case.

# National Freehold Land and Building Society v. Maurice Freeman.

An alleged nuisance by motor-driven machinery gave rise to this which came before Mr. Justice Sargant on April 19th, the plaintiff S clety and their tenant, Battista Bazzılia, claiming an injunction in respect of an alleged breach of agreement, and the defendant, also a tenant of the Society, counterclaiming for

damages for alleged breach of warranty.

MR. STROUD, in opening the case on behalf of the plaintiff, said he ala med an injunction to restrain the defendant from using or permitting to be used on his premises, the first floor of 39 and 40, Mitre Street, Aldgate, any machinery so as to cause a nuirance either to the plaintiffs or the other occupiers of the premises. The plaintiff Society were the landlords, and the plaintiff Barzalia was plaintiff Scorety were the landlords, and the plaintiff Sazzilla was a tenant of theirs who carried on a restaurant business there. The defendant became the occupier of the first floor of the premises under an agreement dated January 15th last year, and he alleged that before entering into the agreement the Society, through its agents, had warranted the premises to be adapted for motive nower. That gave rive to the counterclaim, the defendant contending that in the event of the second plaintiff recovering any damsege, or an injunction being granted, he was entitled to claim against the society for breach of warranty. Prior to January 12th the defendant entered into negotiations with Mesers. F. Hilbury & Co., house and estate agents, of 140. Leadenhall Street, for premises suitable for his business of a buttonhole maker. In an interview with Mr. Hilbury the defendant explained that he required the premises for his business of a buttonhole manufacturer, and also mentioned that he would be using machines, but it was not suggested or brought to the knowledge of Mr. Hilbury in any way that there

was any intention of introducing electric or other power on the premises. In a letter written before the tenancy agreement was entered into the defendant said he had ascertained that there was premises. no electric light installed on the premises, but no reference what-ever was made to electric power. Mr. Johnstone, the secretary of the plaintiff society, and Mr. Hawkins, a rent collector in their employ, had interviews with the defendant prior to the signing of the agreement, and both would tell the Court that though the the agreement, and both would tell the Court that though the defendant said that he would put machines on the premises they understood him to mean treadle or hand machines. Nothing whatever was said about power-driven machines. The defendant asked Hawkins whether there was electric light on the premises, and Hawkins by mistake said that there was, but nothing would turn upon that as the defendant afterwards had a! the stating the content. When the agreement was completed at Means Hillpure's contrary. When the agreement was completed at Mes-rs. Hilbury's office, again nothing was said about power-driven machines. The agreement was for a tenancy of the whole of the first floor of 39 and 40, Mitre Street, and the clause upon which the plaintiffs relied was that the tenant covenanted to do nothing that might cause nuisance or annoyance to the occupiers of acjoining proerty, nor carry on any trade or business except that of a buttonhole maker.

MR. JUSTICE SARGANT: That would imply that he was not to use the premises for the business of a button-hole maker so as to be a nuisance, unless the nuisance was absolutely essential to the carrying on of a button-hole maker's business. The defendant would have to show that it was quite impossible to carry on his business without causing a nuirance.

COUNSEL, continuing, said that the defendant was let into possession, and he proceeded to make arrangements with an electric lighting company to install electric power without consulting the plaintiff society in way.

Mr. JUSTICE SARGANT saked whether the installation was for

both light and power.
COUNSEL said he did not know.

His LORDSHIP said he asked because there must have been a parate installation for power, as power was charged for at a

Counsel said he did not think it mattered, as there was no question that the defendant was working his machines by electric power. Mr. Hawkins visited the premises about some repairs and saw an electrician at work there, but thought it had merely to do with electric lighting. Barzalia wrote to the plaint if society complaining of the nuisance and loss of custom in consequence, and after some correspondence, in which it was suggested that the nuisance might be obviated by more firmly fixing the machines, the present action was commenced.

Both sides agreed that if the Court should hold that the question was one of damages the amount should be fixed by his Lordship, to save the expense of an irquiry.

It was admitted, added counsel, that the defendant had installed

on the premises a 2-H.P. electrically driven machine. Evidence was given in support of counsel's opening statement.

Called for the defence, and examined by MR. FORTUNE, MAURICE FREEMAN said that he had been in business in Old Street, and had used power-driven machines. It was perfectly understood when he took the premises in question that he would be using machines in his business, and the electrically-driven machines made little or no more noise than would hand or treadle machines. The machines he was now using stood on a bed about 3 ft. bigh, and were the best machines that could be got for his trade. There was no better method known in the trade of carrying on his business than the one he had adopted. As a buttonhole maker, he did not think his business could be carried on with less noise. All the large firms used these machines. ment work, and worked on a Sunday. He was now busy on Govern-

Cros-examined, WITNESS said that when he asked whether electricity was laid on on the premises, he did not lead Mr. Hilbury to suppose that his inquiry referred only to electric light. He asked whether there were electric wires on the premises, and he did not suppose that anyone could suppose his inquiry was confined

to wires for electric lighting.

Re-examined, WITNESS said that he made it clear to both Mr. Hilbury and Mr. Hawkins that he would be using motor-driven

machines.

Other evidence was given for the defence to the effect that there was very heavy machinery in the neighbourhood, the working of which could be heard in the street, and that the defendant's electrically-driven machines would make less noise than treadle machines.

MR. FORTUNE, in summing up the defendant's case, admitted that there was undoubtedly some noise caused by these machines, but people could not live in a city without having to endure some noise, and he submitted that the noise in question fell very far

short of a common-law nui-ance.

His LORDSHIP, in giving judgment, said that there had not been the slightest evidence put before him that the negotiations for the agreement of tenancy proceeded on the footing that the defendant was to be entitled to use power-driven machinery on the premises, and he was ratisfied that the plaintiffs' agents never had it brought before them that it was the intention to use such The onus of showing that his business could not be carried on without causing a nuisance was on the defendant, and he had not only not established that proposition, but had not attempted to do so. He had come to the conclusion that the working of these machines was a nuisance, though he thought it was just on the border line of what was a common-law nuisance, and he accordingly granted an injunction to restrain the defendant from so working his machines as to cause a nuisance, and awarded the plaintiff Barzalia £15 by way of damages

The defendant was ordered to pay the costs of the action, but the injunction was suspended for four weeks to enable the defendant to get out of the premiser.

The defendant's counterclaim was dism'ssed, with costs.

# CUNNINGHAM, LTD.

THE petition of W. T. Henley's Telegraph Works, Ltd., for a compulsory order to wind up Cunningham, L'd, electricians, again came before Mr. Justice Astbury, in the Companies' Winding Up Court, on Tuesday. Counsel reminded his Lordship that at the previous hearing he stated that a few creditors had not come into the arrangement that had been proposed. He was now able to state that the whole of the creditors had come in, and the only thing to do now was to dismiss the petition by consent, without

MR. H. E WRIGHT said he appeared for a large number of creditors opposing the petition and he assented.

His Lordship dismissed the petition, without costs.

# NEW ELECTRICAL DEVICES, FITTINGS AND PLANT.

### Variable Speed A.C. Commutator Motors.

MESSES. F. PARKINSON & Co, of Wells Works, Guiseley, near Leeds, have recently issued a new catalogue and price list of their ac. commutator motors, an installation of which at the Government Stamp Printing Works, Hayes, Middlesex, was described in the FLECTRICAL REVIEW, of November 21st, 1913. The makers claim that these are the only British-made motors in which the following features are obtainable: (") A large speed variation, up

# The Firadanac Mining Switchgear.

MESSES. BERRY, SKINNER & Co, of 78, Upper Thames Street, London, E.C., have brought to our notice a new type of explosion-proof switchgear, consisting of a very compact form of cumbined fuse-switch specially constructed for use in those regions of the coal mine where the Home Office Regulations require the apparatus

to be explosion-proof, and preferably fool-proof.

It is conceded by experts that an apparatus which has its component parts in one chamber is better and safer than an apparatus which separates its switches and fuses into different compartments connected by small inlets; moreover, a combined apparatus of the fuse-switch type is obviously more compact, and for a given output has a less cubical content for the retention of explosive gases. It is claimed that the present invention contains a number of points, all important, but never hitherto combined in one piece of apparatus.

The following are the features of the Firadanae explosion-proof, interlocked combined fuse switch with air-break, to which atten-

Great mechanical strength; exceptionally small size for a given output; wide mechane-faced surfaces in comparison with the cubical contents of the cabinet; every current carrying contact is renewable from the front; by an ingenious mechanical device the movable switch contacts can be revolved to present an entirely the movable switch contacts can be revolved to present an entirely clean switch contact after damage; every switch is arranged so that the current is broken upon each pole, upon two contacts in series, and with a parallel action. This is better than a knift-switch with one, or even two, contacts where the current is broken at a point; it is impossible to tamper with the contacts by mischief or accident; the switch has positive quick make-and-break action; axes to the explosion-proof cabinet is impossible until the moving switch contacts and fuses have been made dead; the design is arranged so that the mains may enter at either the top or better is arranged so that the mains may enter at either the top or bottom of the cabinet, and without having to turn the switch "upside down"; the apparatus is fitted with Berry's patent magnetic

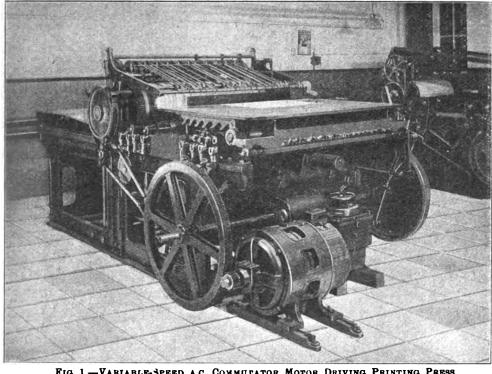

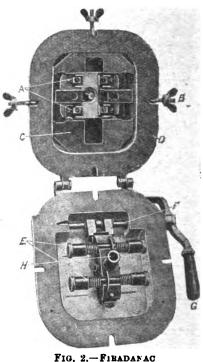

FIG. 1.—VARIABLE-SPEED A.C. COMMUTATOR MOTOR DRIVING PRINTING PRESS.

SWITCH-FUSE, BOX OPEN

to a ratio of three to one, with a shunt speed characteristic throughout the range; (b) this is obtained without the use of any resistances; (c) efficiency practically constant at any speed, and comparable with that of a D.C. motor of equal size. The motors have fixed brushes and no mechanical governor or short-circuiting device of any description is employed.

The motors are provided with exceptionally robust shafts, bearings and commutators, which ensure great reliability in service, and have been designed in five types, covering practically the whole field of the application of alternating current motor driving for industrial purposes. We illustrate in fig. 1 a variable-speed single-phase motor driving a printing press. The speed controller consists of a small oil-immerced transformer which is shown in the illustration. These machines are built under the Punga and Greedy patents.

Punga and Creedy patents.

A serious objection to alternating-current commutator motors in the past has been the difficulty of obtaining satisfactory commutation. This feature has received very careful consideration in the design of the Parkinson motors, and the makers can guarantee the commutation to be equal to that of the best modern direct-current practice. These motors fill a long-felt want in the application of alternating current for industrial purposes.

The firm have recently completed a large extension of their works in order to meet the increasing demands for their manufactures, and the whole of their works is devoted to the manufacture of alternating-current commutator motors.

blow-out fuses. Without a screw-driver or any other tool, these can be re-fused with ordinary copper wire in a few seconds. There is no possibility of accidental shock during replacement.

The switchgear was examined and tested by the Underwriters' Laboratories, Inc., of Chicago, U.S.A., in December last. A sample 20-ampere 200-volt switch was operated 12 times by band, closing and opening a circuit in which a continuous current of 80 amperes at a pressure of 315 volts was passing, first with the swirch cabinet earthed, and afterwards with the generator alternately earthed on the positive and negative side. Strips of copper were placed in parallel with the fuses to prevent the latter from blowing. The contacts were only slightly burned.

The insulation resistance was measured with a 500 volt Evershed.

The insulation resistance was measured with a 500-volt Evershed Megger, and the result was:—Positive to negative, 20 megohms; positive to negative to carth, seven megohms. The two poles of the same switch were connected to the terminals of a transformer, and starting at 800 volts the pressure was gradually raised to 2,000 volts and maintained for one minute. The test was repeated with the transformer terminals connected to the switch contacts and metal case respectively. The insulation satisfactorily withstood this test. The illustration (fig. 2) shows an ironclad fuse-switch cabinet with the cover open; this cabinet is provided with a 14-in. machined flange D, with similar provision on the hinged cover. When the cover is closed and the metal surfaces are together, they are clamped by four equally-spaced wing nuts as at B.

The cover having been closed, the lever  $\omega$  can now be operated by means of the spindle and rock shaft I to throw the rapidby means of the spindle and rock shaft F to throw the rapid-acting toggle joint carrying the magnetic blow-out fuse carriers E into their respective base contacts at A. This operation of closing the switch automatically locks the cabinet by means of the engagement of a male bolt in the centre of the base with the female projecting tube H. It is impossible to open the cover until the bolt is withdrawn by moving the switch to its "off position."

Shrunding of the cable connections in the base to meet the

Shrouding of the cable connections in the base to meet the Home Office requirements is provided by the insulating screens as

FIG. 3.—FIRADANAC SWITCH-FUSE. CLOSED.

To rewire a blown fuse, the magnetic blow-out fuse carriers E can be out-sprung in one second, re-fused and in-sprung into position in under 30 seconds for the complete operation. The apparatus is low in price and simple in construction. Every part is interchangeable; it is "made like a gun."

### Electrically Heated Grip for Steering Wheel.

Electrically heated leather-covered grips for use on steering wheels of automobiles, have been developed by the INTERSTATE ELECTRIC Co., New Orleans, La. The grips are attached to the wheel, as shown in the accompanying illustration, and are

FIG. 4.—ELECTRICALLY HEATED GRIPS.

provided with laces for making them tight. Energy may be obtained from the storage battery of the car, or, if the magneto's rating is high enough, from the magneto.

### Shop Window Reflectors.

A complete series of seven shop window reflectors has been brought out by the GENERAL ELECTRIC Co., LTD., of Queen Victoria Street, E.C., which includes the following types: Shell, fluted scoop, plain scoop, hemispherical, horizontal parabolic, vertical scoop, plain scoop, hemispherical, norizontal parabolic, conic, all of which (except the hemispherical) are made in two sizes, the smaller designed for up to the 30-watt Osram

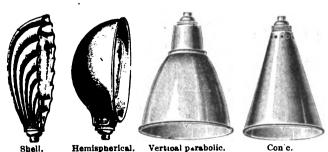

FIG. 5.-G.E.C. SHOP WINDOW REFLECTORS.

lamp size, and the larger for lamps up to the 60-watt size, thus ensuring any pear-shaped Osram lamp of the usual sizes having its correct reflector. All these reflectors have scientific contours, and effectively screen the light from the eyes of persons looking in the shop window.

Special care has been taken to see that the shade carrier ring, which holds the reflector in position, is easily accessible, and a special feature in the case of the deep conic and vertical parabolic patterns is the provision for the necessary ventilation. The high-class nickel plating finish assures the maximum amount of reflection being obtained.

A neat folder, No. F. 1,902, gives particulars of these reflectors,

some of which are shown in fig. 5, in tabulated form.

## ELECTRICAL TRADES BENEVOLENT INSTITUTION.

The report of the Committee of the above Institution for the year ended December 31st, 1914, was adopted at the annual meeting, held at the Institution of Electrical Engineers, on Monday evening. Dealing first with financial matters, the Committee says that for the second year in succession the principle of having the head of a large firm as President of the Annual Festival resulted in a most satisfactory addition to the funds. The total income from contributions for 1914 was £3,139. This, added to the receipts from dividends and other sources, produced a total income of £3,380, as compared with £1,363 in 1913. The subscriptions from members and the number of members have again increased. The result of the year's work has been a net income of £3,127. The following investments have been made out of this sum:—£404 Canada 4 per cent. registered stock, £407 3 per cent. Metropolitan Water Board stock, £925 New Zealand 31 per cent. inscribed stock, £1,071 Bombay, Baroda and Central Indian Railway capital stock, = £2,807, bringing the total of the invested funds to £7,727.

For the sixth year in succession a donation has been received THE report of the Committee of the above Institution for the

funds to £7,727.

For the sixth year in succession a donation has been received from the Electrical Engineers' Ball. Mention is made of the financial and other support received from the electrical Press, and this year for the first time from the general Press.

The working expenses have naturally, in view of the large amount collected, been heavier, but it is a matter of satisfaction that the percentage of the expenses to the amount collected is very much less than in previous years.

The total amount paid out for temporary relief during the year was £253, as compared with £154 in the previous year, the number of grants dealt with being 28. Every person who has applied and who was qualified for assistance received the same. the same.

Employment was found for many of the applicants. The committee has always endeavoured to find work if possible for those who apply for assistance, and in this way the amounts expended on temporary relief are much smaller than they otherwise would be, with the result that the invested funds can be increased more rapidly than otherwise would be the case.

The committee feels that it cannot too strongly impress upon all those connected with the electrical industry how desirable it is that the members of the staffs of firms should join the Institution as members, and it therefore again points out in the report the advantages of membership. It is hoped that the heads of electrical businesses will bring this matter before the members of their staff.

Mr. Hugo Hirst was elected President of the Annual Festival,

1914, and owing to his untiring energies preceding the festival he was able to announce at the dinner that a total sum of over £2,700 had been collected. The chairman's list amounted

over \$22,100 had been concerned to £2,464.

The Chairman in his appeal at the dinner was ably supported by Sir David Salomons, Mr. Wordingham (Vice-President of the Festival), and Mr. Godfrey Isaacs, and as the total amount collected in connection with the result, the total amount collected in connection with the festival, exclusive of the subscriptions of new members who then joined, was £2,741.

then joined, was £2,741.

The benefit which has resulted to the Institution by the system of collectors' books is demonstrated by the list in the year-book. The committee trusts that those gentlemen whose names appear in the list, and who devoted so much time and energy during the year 1914 to assist the collection of funds of this Institution, will continue their much appreciated efforts in the year 1915.

The Institution of Electrical Engineers is thanked for the use of its premises, and the electrical Press for its assistance in the matter of publicity.

use of its premises, and the electrical Press for its assistance in the matter of publicity.

The balance sheet shows that the fund now has £7,727 invested, and £199 at the bank, with £22 standing as sundry debtors, = £7,948. The income of the year from all sources, including dividends on investments (£225), subscriptions, donations, and sale of tickets, etc., for the Annual Festival Dinner, was £3,470. The expenditure was as follows:—Printing, postages, stamps and stationery, £64; secretary's salary and commission and office expenses, £179; 28 grants paid (ranging in value from £1 10s. to £20), £253; cost of Annual Festival Dinner, £100, making the balance carried to the balance sheet £2,875.

Among those present at the meeting were Messrs. E. Garcke (in the chair), Justus Eck. F. B. O. Hawes, H. Bevis, F. H. Nalder, H. Oppenheimer, A. A. Campbell Swinton, and L. G. Tate. The total income for the past year amounted to £3,470, compared with £1,362 for 1913, and 28 grants, totalling £252, were made, as against 14 grants costing £153. The total out-

goings were \$595 (\$400), and the surplus earried to the balance sheet \$2,874 (\$292). The total capital of the Institution on December 31st last was £7,871, against £4,996. At present there are about 170 members. Messrs. Sugden and Hextall were re-elected hon. solicitors, and Messrs. Price, Waterhouse and Co. hon. auditors. Lord Vaux of Harrowden, Lt.-Col. H. M. Leaf, and Messrs. Guy Burney, H. Bevis, H. H. Berry, F. J. Walker, R. J. Wallis-Jones, and S. D. White were re-elected to the committee of management, and it was resolved that special effort be made to induce Mr. E. J. Clark to withdraw his resignation, owing to the valuable services he had rendered in the past. It is desired to fill vacancies on the committee by representatives of electrical firms. committee by representatives of electrical firms.

### WAR ITEMS.

Carlisle Supply Men.—The following is a complete list of employes of the Carliale electricity department now serving with the Colours; these form 35 per cent, of the total. Those still employed are provided with a badge indicating that they are engaged on public service.

engaged on public service.

Baynham, H. P., station superintendent, Royal Engineers.

Hay, J. H., chief clerk, 4th East Lancs. Howitzer Brigade Cumberland R.F.A.

Fraser, W., storekeeper, 7th Batt. Border Regiment.

Stephens, G., assistant storekeeper, Border Depôt.

Thompson, W. V., consumers' assistant Army Service Corps.

Ballantyne, H. S., switchboard attendant, 4th Batt. Border Regiment.

ment.
Fairclough, F., meter reader, 4th

Mannion, J., jointer, 4th East Lancs.
Howitzer Brigade Cumberland
R.F.A.

Baxter, R., stoker, 2nd Batt. Border Regiment.
Berry, M., coal trimmer, 4th Batt. Border Regiment.
Wright, A., coal trimmer, Royal Engineers.
Clark, W. H., porter, 4th Batt. Border Regiment.
Sanderson, R. H., engine room attendant, 4th East Lancs. Howitzer Brigade Cumberland R.F.A.
Simpson, J., apprentice, 4th East Lancs. Howitzer Brigade Cumberland R.F.A.
Todd. G., apprentice, 4th East Lancs. Howitzer Brigade Cumberland R.F.A.
Cem, R., apprentice, Royal Engineers.

Germans and Russian Cables.—According to the Novoie Vremya, the subscription of the house of Bogan & Co., of Moscow, of 300,000 roubles for war charities, has brought the question of the nationality of the house under discussion. It is undoubtedly the nationality of the house under discussion. It is undoubtedly considered to be German, and two members of the board, M. Ph. and G. M. Mark, only became naturalised Russians after the war began. Further, after the outbreak of the war, a syndicate was formed in Petrograd called the United Cable Factories Co., in which the chief part is played by the house of Bogau, along with the German house—Felten & Guilleaume, of Mannheim. This synthe German house—Felten & Guilleaume, of Mannheim. This syndicate, says the journal quoted, now dictates the prices of copper and copper products in Russia, being part owner of the Bieloretzk, Kolchugin and other factories which control practically all the copper goods produced. Controlling also rich copper mines of the Caucasus and the Urals, Bogaus dispose of immense stocks of copper, and if the syndicate has raised the price of copper by about 50 per cent., and of copper goods by 75 per cent., the lion's share of the profit is passing into the pockets of Messrs. Bogau & Co.

A Hungarian Company and the War.—The report for 1914 of the Hungarian Felten & Guilleaume states that after a short period of stagnation the industrial and economic life of the country ssumed a regular course with the exception of a few branches Instead of a dearth of work a scarcity of workers had arisen, and the difficulties resulting therefrom, as well as from the limitation the difficulties resulting therefrom, as well as from the limitation in the production of coal and the increased cost of manufacturing, brought about a diminution in the profits. The gross profits amounted to £37,000, as compared with £41,000, and the net profits were £17,000, as against £28,000 in 1913, the dividend being 10 per cent, as contrasted with a rate of 15 per cent, in the previous year. At present the company is still engaged directly and indirectly on the execution of war orders and would be able to keep the works in full operation were it not for the lack of copper owing to the requisition of this material by the Government.

English Capital in Germany.—The chairman of the Mix and Genest Telephone and Telegraph Co., of Berlin, was asked at the recent general meeting why the company had registered a proposal for the liquidation of the Lampson Co., in which the former is financially concerned. In reply it was mentioned that the telephone company was at present unable to work with an undertaking in which Englishmen were interested, which was now everywhere exciting attack, and was excluded from official orders. After the removal of the English participation it was added that the Lampson Co. would presumably resume business activity, and the hope was expressed that favourable results would then be

More Electrical Men Wanted .- The 204th Field Company R.E. and 40th Divisional Signal Company R.E. are now being formed and training at Norbury, S.W. Major Minshall, R.E., M.I.E.E., is in command of the 204th Field Company. There are vacancies in both of these companies for electricians, wiremen, telegraphists and mechanics. Applications for particulars or for enlistment should be made to the Norbury Golf Club House, Norbury, S.W.

Board of Trade Assistance.-List No. 16 (week ending April 10th) has been issued giving particulars of inquiries received for sources of goods by the Commercial Intelligence Branch of the

Municipal Repair Shops.—The Manchester civic authorities are making every effort to assist the Government in increasing the output of war munitions, and on Friday a special sub-Committee of the Corporation Electricity Committee offered the War Office the use of the repair shops at the Stuart Street generating station. This is a large building, containing lathes and other important machinery. The War Office representatives in the city have expressed the opinion that the building is most suitable for

The Liverpool Tramways, Electric Power and Lighting Committee has passed a resolution that the Committee desires to do everything possible to assist the Government in the production of munitions of war, and that the Corporation workshops at Lambeth Road be placed at the disposal of the Government for this or for any other purpose, such as repairs to motor transport vehicles, &c.

Contravening Lighting Orders. — The first prosecution in Leeds for contravention of the Military lighting restriction orders, under the Defence of the Realm Act, occurred last week, when a tradesman was fined £10, with the alternative of eight weeks' imprisonment. When the defendant said he would pay in a week the Stipendiary Magistrate said he must pay that day or go to prison. The defendant had defied the police.

Personal.—Mr. J. H. Thomas, A.M.I.E.E., who has recently returned to England from the Far East has been granted a commission in the Royal Engineers, and is attached to the 204th Field Company now to include the North American Company now to include the North American Company now to include the North American Company now to include the North American Company now to include the North American Company now to include the North American Company now to include the North American Company now to include the North American Company now to include the North American Company now to include the North American Company now to include the North American Company now to include the North American Company now to include the North American Company now to include the North American Company now to include the North American Company now to include the North American Company now to include the North American Company now to include the North American Company now to include the North American Company now to include the North American Company now to include the North American Company now to include the North American Company now to include the North American Company now to include the North American Company now to include the North American Company now to include the North American Company now to include the North American Company now to include the North American Company now to include the North American Company now to include the North American Company now to include the North American Company now to include the North American Company now to include the North American Company now to include the North American Company now to include the North American Company now to include the North American Company now to include the North American Company now to include the North American Company now to include the North American Company now to include the North American Company now to include the North American Company now to include the North American Company now to include the North American Company now to include the North American Company no to Company now training at Norbury.

Mr. E. A. Shaw, formerly assistant engineer to the Burton-on-Trent and Ashby-de-la-Zouch Light Railway Co., has been gazstted Lieutenant in the Royal Garrison Artillery.

By wireless from Berlin comes the information that the Iron Cross has been conferred upon Prof. Boentgen in acknowledgment of his eminent services to surgery. The professor was decorated on his 70th birthday.

The London Gazette, on Tuesday, contained the following announcements:

### TERRITORIAL FORCE.

No. 2 Electric Lights Companies.—Neville L. Phipps (temporary)

No. 2 Electric Lights Companies.—Neville L. Phipps (temporary).

Cyril R. Norman (temporary).

No. 3 Electric Lights Companies.—Percy H. Bartlett (temporary), Cuthbert L. Fox (temporary).

No. 4 Electric Lights Company.—George Frederick Bale to be Second Lieutenant. Dated April 21st, 1915.

London Electrical Engineers.—Second Lieutenant Hubert F. G. Roose is seconded. Dated April 10th, 1915.

Roll of Honour.-Information has reached Liverpool that two more tramway men employed by the Corporation have been killed at the front. The roll of honour of the tramway staff is now 17 killed and 40 wounded out of 1,000 men.

Information has reached Ecoles of the death of Private E. Ashton, of the 2nd Batallion Lancashire Fusiliers, who was shot though the head by a German sniper. He was a single man, and for 17 years had been employed in the electricity department of the Ecoles Corporation.

Sergt. Fred Helm, who was employed in the shipping department of Mesars. Dick, Kerr & Co., Strand Road, Preston, has been killed in action. The deceased, who was 29 years of age, has left a wife and three children. He was recently awarded the D.C.M., and promoted sergeant. He had seen service in India and South Africa.

Corporal A. E. Irving, of Burnley, a local tramway conductor, has been awarded the D.C.M. for his work in the Neuve Chapelle

has been awarded to B.C.M. for his work in the receive Chapters of age.

Private C. J. Husband, aged 20 years, Pendleton, formerly employed by the British Westinghouse Co., has been invalided home, suffering from the effects of rheumatic fever, which he contracted through exposure in the trenches.

Private Thos. Herbert Hilton, 3rd Border Regiment, of Oldham, has been killed in action. He was 24 years of age, and was formerly employed as a conductor on the Oldham Corporation Tramways. He was killed on April 10th, as his Quartermaster reports—"while doing his duty bravely and nobly." Private Foeter Irving, 1st Manchester Regiment, who was also a tramway conductor at Oldham, was shot in the head and killed while going to the trenches on April 7th. He had been through the battle of Neuve Chapelle

Neuve Chapelle.
Second-Lieut. Sidney Gudgeon, of the Manchester Regiment, recently reported as having been wounded in France, was for three years a student in the Manchester School of Technology (Faculty of Technology of the University), where, in 1912, he was awarded the Certificate of the University in Electrical Engineering.

"Noise and Vibration caused by Electric Plant." -With reference to the case reported under this heading in our "Legal" section last week (page 545), a correspondent informs us "Legal" section last week (page 545), a correspondent informs us that the nuisance really arose from the noise created by the exhaust from a gas engine driving the electric lighting plant at the picture palace. The writer is anxious that electrical plant, should not carry a burden of blame which properly belongs to

# THE CASE FOR THE ELECTRIFICATION OF ENGINEERING WORKS.

By ERNEST P. HOLLIS, A.M.I.E.E., A.Amer.I.E.E., M. Assoc Min. E.E.

For very many years the opponents of the electrification of engineering works have sought to make out their case on the ground of low power costs. It will be within recollection that some years ago almost every railway station in the country was placarded with announcements by firms of gas-engine makers containing the legend "10 B.H.P. for 1d. an hour." Possibly under exceptional circumstances such a claim could be justified; indeed, if it came to be a question of low power costs, the writer could point to a case in which, by the introduction of electrification, a large works is obtaining the whole of its power at a cost of minus £1 a week. For some time electrical engineers found it difficult to make headway against these assertions, and then only by forcing upon the owners of engineering works a realisation of the large losses incurred in line shafting. Before the introduction of the electric motor little care had been bestowed on line shafting, but electrical engineers soon showed that there were exceptional cases in which 60 per cent. of the total power generated by the engine was wasted in the shafting, and 30 per cent. was a common figure. This appreciation of heavy line-shafting losses led to a number of conversions to electric drive.

Later on, when factories grew larger, a further disadvantage of a drive from long lengths of shafting demonstrated itself. The engineer could not say: "I will put my machine here because it is the best place for it," but had to say: "I cannot put my machine here, although I would like to, because it would be too costly to bring up the line shafting; therefore, I must go near to the line shafting."

increasing competition and the necessity for an intelligent arrangement of the machinery so that work went orderly through the shops and never had to retrace its steps, the engineer began to chafe at the restrictions imposed upon his arrangements by the line shafting, and to look more favourably upon the electric drive, even though its opponents had asserted that it cost slightly more per B.H.P.hour than other methods of drive. In consequence, he first of all electrified a few outlying machine tools without committing himself to the larger scheme of electrification advocated by electrical engineers, and he experimented with these tools. He found that, contrary to what he had been told, they needed no experts to work them, and that the operations involved in the control of the motor were so simple that they could be safely entrusted to the machine operator. At the same time he succumbed to the temptations of the small electric tools which were pressed upon him, and found, no doubt to his surprise, that an extremely large number of operations which had hitherto involved great labour and inconvenience could be performed by handy little electric drills, grinders and similar machines. He experienced for the first time what a convenience it was in the case of heavy work to be able to take the tool to the work instead of the work to the tool. Probably he was still unconvinced that he had not done all that he could do towards the improvement of the driving of his factory. He was still under the impression that as long as he did not press the extension of the line shafting too far he was not incurring undue losses; at any rate, he was not incurring losses greater than manufacturers of the gas, steam or oil engine told him would be incurred in the transformation of the energy in the steam, gas or oil to electricity and transmitting it and subsequently converting it to mechanical power. But sooner or later he was persuaded by the electrical engineer to test the power taken by the shafting running light and under other conditions, and to compare it with an individual drive. How was he to do it? Obviously, responded the electrical engineer, by installing temporarily an electric motor and measuring the power taken by the motor. The experiment showed that the electrical manufacturers were right. The line shafting often took an excessive amount of power to drive it, even on light load, and there was a great waste of power in keeping the whole of the shafting going when, perhaps, only one machine was required to be run. A few

further tests demonstrated that the aggregate power required by individual electric motors was less than had to be applied at the central point for driving through a line of shafting.

But this experiment brought home to him something about the electric drive that he had not appreciated before. For the first time he could conveniently measure the power taken by a machine. For the first time he could say whether that machine was taking more power than the manufacturers had asserted. For the first time he was able to make adjustments in the running of the machine, and able to tell whether those adjustments resulted in an increase or decrease in the amount of power consumed.

With the introduction of the new steels with high cutting speeds, he found that his existing power arrangements were inadequate to run the machines under their new conditions. He experienced difficulties in the cutting of metals of varying degrees of hardness due to the slipping of the belts and the poor speed regulation. It was then not long before the advantages of the electric drive in respect of speed control were brought home to him.

Of course, one of the best canvassers for electrification in engineering works has been the electric crane. Every engineering works of any size employs electric cranes which have often been installed before the conversion of the main drive to electricity.

The foregoing remarks have outlined the different steps involved in the education of the factory owner to the advantages of the electric drive, and up to the present only the main benefits accruing from electrification have been discussed. These are now fairly widely appreciated amongst factory owners, and it is practically only in those few cases where the owner himself is interested in the manufacture of prime-movers suitable for driving from a central point, that the consumers' engineer will find any antagonism to the electric drive. There are, however, numerous points which can be brought home with advantage to assist a consumers' engineer in the securing of new consumers, and an endea-vour has been made below to set out briefly telling points which can beneficially be put before potential consumers.

Elimination of Line Shafting Losses.—The elimination of line shafting losses has already been discussed. A consumers' engineer has, of course, to make sure of the extent of line shafting in the works before he can use this argu-In very small works it is sometimes the case that a central drive would not be greatly inconvenient, and in these instances the argument of the elimination of line shafting losses carries no weight.

Tools Worked to their Maximum Output .- The factors which enable an individually-driven tool to be worked to its maximum output are :-

(a) The overload capacity of the motor.
(b) Better speed regulation, permitting metals of varying degrees of hardness being treated at different cutting speeds.

(c) The absence of slipping belts.
(d) The ability to make rapid starts, stops and reversals.

(r) The ease of control from convenient points.

(f) Independence of auxiliary details.

Free Arrangement of Tools.—It is of great importance in a modern engineering shop that there shall be the fullest freedom in the arrangement of the tools, not only to enable the work to be carried through the shops in the best sequence of operation, but to permit the changing of the machine tools for larger or different ones.

Provision of Facilities for Adding New Tools.—It often happens in laying out an engineering shop that it is not possible to foresee the extent or the direction of the developments of the work. A new class of work comes along; a greater demand for a particular class is experienced than had been anticipated; or the demand for certain articles has not realised expectations. In any of these contingencies it may be desirable to introduce new tools or to transport older ones, thrown into desuetude through lack of work, to another part of the shop. When tools are tied to the line shafting, the rearrangement or the introduction of new tools is a matter of difficulty, and the convenience of being able to put down a tool where one likes without any consideration of line shafting is a matter of great moment.

Ability to Measure Power .- One of the greatest advantages introduced by electrification is the great ease with

which power can be measured. Not only can the power taken by the machine on full load be ascertained and adjustments made which permit a reduction in the amount of power without any effect upon the quality or quantity of the work, but the light load readings can be taken, which offer a reliable criterion of the mechanical efficiency of the tool, and any deterioration in the gears or other defects can be instantly detected.

Facilities for Overtime and Week-end Work .- In many industries repairs and maintenance work is carried on during the week-end; indeed, in textile mills and in several other works the writer has visited, special engines have been installed to save the main engine being run during the week-The disadvantages of having to keep an engine-room and boiler house staff in attendance either during overtime or at the week-end in order that one or two small machines can be run for repair work are so obvious as to make it not worth while to pursue them further.

Elimination of Belts.—Probably in very few engineering works would it be possible or economical entirely to eliminate belts; but by electrification the number can be considerably reduced. Some belts are advantageous in the respect that they form an admirable friction clutch, but they have their many disadvantages, which are well known; while, in addition, there is the cost of maintenance.

In a big engineering works, belt-driven from long lengths of shafting, the handling of work is made considerably more difficult.

No Restrictions upon Head Room.—Electrically-driven cranes are a sine qua non in all engineering works of any magnitude, and anything which interferes with rapid and efficient transport of work about the shops is a decided dis-Line shafting and belts often interfere with the transportation of work.

Increased Safety to Operators.—An individual motor drive affords the fullest protection to the operator; he has only to move a switch. An individually driven machine is in no danger of being started up unexpectedly by the creeping of belts from loose to tight pulleys, the sticking of clutches, and the starting up of line shafting. setter is protected against the inadvertent starting of a machine, and by taking out the motor fuses, assurance can be made that no unauthorised person can start up the machine. Lastly, the operation of belt changing, which has

been a source of many accidents, is eliminated.

Non-Obstructed Lighting.—The output of a modern factory is considerably influenced by the lighting conditions. Consciously or unconsciously a workman works much better in a properly-arranged light. That light must not be too strong and not too weak, and the moving shadows which are thrown by belts are a source of great annoyance. illuminating engineers will know, a works full of belts and shafting offers some trying problems in illumination.

Improvement in Environment.—The elimination of noisy belts and shafting brings about an appreciable improvement in the surroundings. Distracting noises due to belts and shafting are absent, and the workman can concentrate more fully on his work. The incessant din of belts and shafting is not conducive to good workmanship, and with the electric drive the workman does not stand in the midst of a mass of overhead revolving pulleys, moving belts and noisy transmission, permeating the atmosphere with oil Many manual operations, such as belt spray and dust. changing and replacement, are entirely eliminated, and these, in conjunction with other advantages, materially add to the improvement of the lot of the workman.

The foregoing discussion of the merits of the electric drive covers engineering works in general, and there must be in each case special advantages peculiar to the industry itself. As an example of these, the writer was recently visiting a works in which steam haulage had been employed. The steam engine had been replaced by an electric motor. On examining the setting of the relays of the motor, the writer noticed with surprise that although the motor was of 150 H.P., the relays were actually set for 100 H.P. On making inquiries as to the reason for this, he was told that the tubs had to be drawn round a number of difficult curves, and with the steam haulage when the tubs came off, as they frequently did, the track was badly damaged. But with the electric haulage the power they required had not

been so great as had been anticipated, and they set the relays to such a low point that the slightest disarrangement in the trucks tripped the relays. In this way the relays which normally are introduced to protect the motor, were utilised to protect the mechanical side of the transportation scheme; and the electrical engineer said that this one advantage alone decided him in favour of electric haulage in all circumstances.

In conclusion, the writer would warn consumers' engineers, if they need any such warning, of the diffi-culties of dealing with the very small consumer. The man who has a small works driven from a small town It is of no use gas-engine is very hard to convince. attempting to show that for small consumers with power at 1d. per kw.-hour and gas at 1s. per thousand cb. ft., the electricity bill will be smaller than the gas bill. Possibly it will not. Such a consumer counts for nothing the time lost in starting the gas-engine in its recalcitrant moments; he takes no account of the labour involved in its cleaning, or of the time he has to keep it going to run, say, a small lathe after the whole of the other tools in the shop have been shut down, or of the space taken up in his shop by the gas engine plant. It is bad business to convince such a man against his will and then for him to find that electrification is costing him more. Rather is it advisable to deal frankly with him and tell him that under the circumstances electricity cannot compete with the gas; but, nevertheless, there are a number of uses to which electricity could be put in his shop, such as driving portable drills, and so With these he can take advantage at least of some of the benefits accruing from electrification, and when the time comes for an extension of his works his past experience with electricity will incline him towards it, even if he is aware that his electricity bill will be slightly larger than a gas bill.

# BUSINESS NOTES.

Osram "Atmos" Lamps. - THE GENERAL ELEC-TRIC Co., LTD., announce that owing to continued progress in the manufacture of Osram gas-filled lamps, a name has been registered for this class of lamp. In future all Osram half-watt lamps will be marked "Made in England. Osram Atmos type, Patent G.E.C."

Stoker Contracts,—Messes. E. Bennis & Co., Ltd., report that the ordinary commercial demand for their machinestokers, coal elevating and conveying plant has been thoroughly well maintained. A list of contracts recently received covers a very wide range of industries, Corporation electricity stations coming an easy first. We select the following typical examples:—Nobel's Explosives, Ltd., Powder Factory, South Wales (per Mesers, Ya'es and Thome.—Thirty-two coking stokers and furnaces for 8-fs. diameter Lancashire boilers.

Manchester Corporation Electricity Department, Bloom Street Statin.—Relinking two pairs of chain-grates of another make with the Bennis patent long-life-link. (Repeat order.)

Disto, Stuart Street Station.—Relinking four chain-grates of another make with the Bennis patent long-life links. (Repeat order.)

Huddersfield Corporation Electricity Station.—Four pairs of chain-grate stokers for Stirling boilers.

Burton-on-Trent Corporation Electricity Station.—Two sprinkler stokers self-cleaning compressed-air furnaces. (Repeat order.)

A railway company's power station.—Two sprinkler stokers and compressed air furnaces. (Repeat order.)

Pritchette & Gold, Dagenham, Romford (per Stirling Boiler Co.).—Two chain-grate stokers for dtirling boilers.

Blackpol Corporation Electricity Station.—Bucket elevator with cast iron receiving hopper and discharge shoot. This plant consists of a broker elevator to raise 10 tons of cost per hour and deliver it in an overbead bunker with a capacity of 170 tons of cost. As the cost passes from the bunker it will be weighed in an automatic weighing wohine and delivered into the mechanical stoker hypers. The bunker is to be built out of reinforced brickwork and concrete.

The Dowson & Mason Gas Co., Ltd., alma Works, Levenshulme, Manchester.—Coal and ash-handling plant for India. This plant consists of a Bennis bucket elevator and U-link chain conveyor for receiving the coal from the ground level and delivering it into hoppers for a range of gas producers at the rate of Stoker Contracts.—Messes. E. Bennis & Co., Ltd.,

elevator, which raines them into an overneau which they fall by gravity into railway trucks.

The Consolidated Diesel Works. - The Financial Times understands officially that a sale has been completed of the Ipswich works of the Consolidated Diesel Engine Manufacturers, Ltd., for the winding up of which an order was made on July 7th last. The purchasers are Messrs. Vickers, the well-known armament and engineering company.

For Sale.—The Manchester Guardians have for disposal one 36-I.H.P. vertical Marshall & Sons' steam engine, driving by belts; one 20-kw., D.C. generator at 205 v.: and one 3-kw. booster at 75 v. Tenders by May 6th. Particulars are given in our advertisement pages to-day.

Book Notices .- Key to the London Telephone Directory. Vol. II, No. 1. London: Stone & Colquhoun, Price 2s. net.—
Knowing a person's telephone number, but not his name, the
difficulty of finding out who he was without ringing him up and
putting the question to him was practically insuperable until this
useful "Key" was published; for who would essay the stupendous

difficulty of finding out who he was without ringing him up and putting the question to him was practically insuperable until this useful "Key" was published; for who would essay the stupendous task of hunting through the pages of the Telephone Directory for the number referred to? However, nowadays it is a simple matter. With the ald of this key, one not only finds at once the whole of the numbers at each exchange brought together in consecutive order, but also, in this new edition, besides the page, the column in which each number will be found is indicated. Where more than one use the same telephone number, each has a separate entry. A new edition will be published immediately after each official Telephone Directory. This is emphatically a case of a want well filled. A buyers' guide forms an appendix to the Key.

Submarines, Torpedoes and Mines. By W. E. Dommett. London: Whittaker & Co. Price 1s. net.—This is an excellent little book for the general reader who wants to know something about the construction and operation of the "submarine vessels" referred to in the title. It is not so technical as to present difficulties to the layman, and, on the other hand, it is sufficiently technical to appeal to the engineer. It does not contain much matter relating to the electrical equipment, though this is indispensable to the operation of submarines, which present a notable example of the operation of submarines, which present a notable example of a requipped with gyro compasses and other motor-driven appliances, and electric cooking apparatus, as well as wireless telegraph installations in some instances. We can recommend the book as both timely and interesting.

"101 Successful Selling Suggestions" is the title of a little

iustallations in some instances. We can recommend the book as both timely and interesting.

"101 Successful Selling Suggestions" is the title of a little brochure issued free to its 1,233 members by the Society for Electrical Development, of New York; it is claimed to be entirely different from anything ever published before, and to contain ideas which have been selected from 750 that were offered (and paid for at the rate of \$1 each). The cost of production has exceeded \$1.000. The items cover a wide range of subjects, and in many cases naturally the proposals are not adapted for use in this country; but there is no doubt that many useful hints can be picked up from the booklet, and that where they are not directly applicable to our conditions they contain food for thought, which may lead to profitable results.

may lead to profitable results.

Annuaire pour l'An 1915. Paris: Gauthier-Villars & Cie. Price
1 fr. 50 net.—The Annuaire of the Bureau des Longitudes for this year contains a mass of tables relating to geography, metrology, astronomy, &c., physical and chemical data being reserved for next year. A special article by M. G. Bigourdan deals with the methods

of testing mirrors and lenses exhaustively.

Liquidations --THE CHINNERY ENGINEERING Co., LTD. (late the Chinnery Signs (1909), Ltd.).—A meeting will be held on May 18th, at Essex Wharf, Durward Street, Whitechapel, E, to hear an account of the winding up from the liquidator, Mr. H. D. Sheldrake.

Particulars of claims must be forwarded by May 31st to the liquidator, Mr. J. Jeffery, at 106, Cannon Street, E.C.

THE CONSOLIDATED DIESEL ENGINE MANUFACTURERS, LTD., Aldwych, W.C.—Last day for proofs for dividend, May 4th. Liquidator, Sir W. B. Peat, 11, Ironmonger Lane, E.C.

Catalogues and Lists.—ELECTRICAL ALLOY Co. Morristown, New Jersey.—Leaflets relating to "Calido" and other resistance materials for electrically-heated devices, instru-

MESSES. FERRANTI, LTD., Hollinwood.—Binder containing eight new lists describing and giving prices, code-words and weights, for their various types of C.C. ampere-hour meters for house service.

THE ELECTRIC SUCTION CLEANER Co., 56, Victoria Street London, S.W.—Folder giving particulars and prices of the Frant "Premier" electric suction cleaner.

MR. G. BRAULIK, 8, Lambeth Hill, London, E.C.logues of specialities made by log. Luigi Magrini, of Bergame, for low and high tension overhead construction, also switches and circuit-breakers. Mr. Braulik has secured the sole selling rights for these manufactures, and will be pleased to send copies of the catalogues, all of which are fully detailed in the French language and illustrated, to parties interested.

and illustrated, to parties interested.

MESSES. REAVELL & Co., LTD., Banelagh Works, Ipewich.—
Leaflets Nos. 69 and 70. The former illustrates and describes a small air compressor, which was originally designed for starting gas and oil engines, and the latter a type of machine for much higher pressures (1,000 to 1,300 lb. per sq. in.), for filling the receivers for starting Diesel engines. We understand that there is a demand for these machines in other fields; for instance, the No. 69 is serving well in public or private garages for pumping up motor-car tires, and is also used for many other purposes where small quantities of air up to pressures of 250 lb. per sq. in. are required. Both of these types of machine are constructed to be independently driven by an electric motor or by a paraffin or petrol engine.

We have just received from the GENERAL ELECTRIC Co., LTD., we have just received from the GENERAL ELECTRIC CO., LTD., a useful piece of topical advertising literature, which takes the form of a tough paper folder measuring only 5 in.  $\times$   $3\frac{1}{15}$  in. when closed, and having the whole of the interior  $(10\,\mathrm{in}\,\times$   $8\frac{1}{16}$  in.) devoted to illustrations and descriptions of German and British aircraft. The letterpress is confined to the question of distinguishing different machines. Copies of the folder can be obtained on application to the company's publication department, 67, Queen Victoria Street, E.C. Two of the illustrations show respectively a fleet of aircraft dropping bombs, and the other a "Freezor" electric fan providing a refreehing breeze. The words applying to the latter are "Keep cool in case of a heat wave," and to the former "Keep cool in case of an air raid."

MESSRS. OREDENDA CONDUITS CO., LTD., Chester Street, Aston, Birmingham.—Descriptive circular detailing the "Credenda" system of electric heating and ventilating as installed at the premises of the company's London agents, 219, Tottenham Court Raad W.C.

premises of the company's London agents, 219, Tottennam Outre Rad, W.C.
MESSES. BAGSHAWE & Co., LTD., Dunstable Works, Dunstable.—
Illustrated circular relating to their "B.B." chain, and showing views of the works.

Prices Advance.—THE WALSALL ELECTRICAL Co., L/TD., announce that owing to the increase in cost of production they have withdrawn all outstanding quotations as from April 21st for small meters, and that their prices will be increased by 20 per cent. from that date.

Bankruptcy Proceedings .- W. Walker (D. Smith and Co.), dealer in electric lamps, formerly of 2 and 3, Red Lion Court, Fleet Street, E.C., but whose present business address cannot be accertained.—Trustee, Mr. E. S. Grey (Official Receiver, Carey

Street, W.C.), released March 25th, 1915.

C. WRAY, mechanical and electrical engineer, Bradford.—Last day for proofs for dividend May 1st. Trustee, Mr. W. Durrance, Official Receiver, 12. Duke Street, Bradford.

G. J. T. J. PARFITT.—At the Bristol Bankruptcy Court on Friday

G.J.T.J. PARFITT.—At the Bristol Bankruptcy Court on Friday last, bankrupt, an electrical engineer, examined by the Official Receiver, stated that he had filed an amended statement of affairs, showing gross liabilities, £4,973; deficiency, £2,616; assets, £1. He commenced business in Denmark Street in 1888 with his brother, as Parfitt, Webber & Co. They paid £320 for the business, and subsequently he and his partner put into the business further capital to the amount of about £2,600. In 1912 his partner went to South Africa, and the business was made over to the Colston Electrical Works. In consideration he received £1,650 in £1 ordinary shares. The primary reason for selling the business was to compensate his Works. In consideration he received £1,550 in £1 ordinary shares. The primary reason for selling the business was to compensate his sister in respect of a guarantee to the bank for £300 which she had been asked to pay off. He entered into a contract to supply electrical fittings, plant, and buildings to the Bristol International Exhibition for the pageant. He made a net loss of £25 in respect of the contract, and he owed £95 for goods in respect of it. He did not supply goods to the Exhibition, but his loss was for work done as consulting engineer. The main cause for his failure was the failure of the exhibition company, of but his loss was for work done as consulting engineer. The main cause for his failure was the failure of the exhibition company, of which he was a director without fees or salary. He had charge of the electrical installation, and all exhibitors had to take current from him. He expected to make £1,000 profit. He held £750 first debentures, £710 second debentures, and £271 ordinary shares. A judgment for £551 was obtained against him in respect of guarantees. Since the war began his trade had been cut off, and he estimated that he had lost orders to the amount of £2,500. The examination was adjourned until May 14th

The examination was adjourned until May 14th.

J. W. and T. W. TATTEBSALL (Tattersall & Tattersall, electrical engineers, Willesden, N.W.).—An application for debtors' discharge

will be heard on May 11th at Carey Street, W.C.

Russia.—A large Russian technical agency office in Moscow, which has hitherto dealt exclusively with Germany, desires to represent United Kingdom manufacturers of centrifugal pumps, electric motors, &c. Inquiries should be addressed to the British Consulate-General at Moscow.

Trade Announcements. — Mr. L. H. PARKER, formerly with the General Electric Co., of America, and for the last 10 years with the Stone & Webster Engineering Corporation, has been appointed President of the Spray Engineering Co., of Boston, U.S.A., which company has sent us bulletins dealing with its equipment for cooling condensing water and air washers for turbine generators.
Premises at Beehive Corner, Cranbrook Road, Ilford, have been

opened by MESSRS. BOWES & Co., electricians.

The Argentine Republic.—There was a very heavy decline last year in the importation of electrical goods into the Argentine Republic, the official returns lately to hand showing a total of only £1,405,000, as contrasted with £2,022,000 in 1913.

# LIGHTING and POWER NOTES.

Barking.—PRICE INCREASE.—The U.D.C. has decided upon a temporary increase of 10 per cent. in the charges for current, except in the case of power users consuming over 8,000 units per month, when the increase is to be at the rate of 5 per cent.

Barnsley. - Proposed Extensions. - The borough electrical engineer has prepared a scheme of proposed extensions at the electricity works.

Bolton.—L.G.B. INQUIRY.—An inquiry was to be held this week into an application for sanction to borrow £45,032 for the purposes of the electricity undertaking.

Arbroath.—Public Lighting, &c.—The T.C. is to experiment with gas and electricity for street lighting. Recently the Lighting Committee resolved to ask the Gas Works Committee to state at what figure it could supply gas lighting if necessary, and if thought advisable, to take the place of the present electric lighting of the streets, and the Council has decided to test the two systems.

A Sub-Committee is to meet representatives of the Arbroath Electric Light and Power Co. in regard to the assessments on the electric mains; the company holds that the assessment should only be charged on one-fourth of the valuation instead of the full rates being charged, and points out that there is a charge of £43 for water assessment on the mains while the company paid direct for all water consumed by it. If the Council will strike out the assessment of £43, the company is prepared to settle rather than have any further dispute over the matter.

Bedford.—Power Supply.—The T.C. has decided that current for power and lighting combined supplied to manufacturers taking 300,000 units and above per annum, shall be charged 1d. per unit, subject to a scale of discounts for prompt payment of accounts, varying from a deduction of 2 per cent. for a load factor of 12 per cent. or over, to 20 per cent. for a load factor of 20 per cent.

Boston.—E.L. SCHEME.—The R.D.C. has consented to the application of Mr. R. A. Smith for a prov. order for electric light at Skirbeck, Fishtoft, Freiston, Skirbeck Quarter, Wyberton, Frampton and Kirton, but the order, by arrangement with the B. of T., is not to take effect until after the war, to prevent capital being locked up in private enterprise.

Carlisle.—CIVIC OPENING OF EXTENSIONS.—At the ceremonial opening of the electricity works extensions by the Mayor, Mr. F. P. Dixon, which took place recently, the visitors, under the guidance of Mr. Fredk. W. Purse, the city electrical engineer, made a general inspection of the works, visiting the new buildings, where the recently installed plant was set in motion by the Mayor. His Worship also formally unveiled a brass tablet commemorating the occasion. Afterwards the company adjourned to the showroom, where Mr. Gibbings, who presided, said it was interesting to know that the output in units in 1913-14 was 3? millions, and this year they hoped to record four millions. As an indication of the greater efficiency of modern plant and machinery, the engineer told them when the extension scheme was fully completed they would have 17 times the original capacity, at only five times the cost; he concluded by proposing a vote of thanks to the Mayor and Mayoress for their attendance, and by presenting the Mayor, on behalf of Messrs. J. Laing & Son, the building contractors, with a handsome silver table lamp.

Mr. J. W. Nicholson, deputy-chairman of the Electricity Committee, seconded the vote of thanks, which was supported by Mr. J. W. Laing, and Mr. P. N. Rand of the British Westinghouse Co.

Sir Benjamin Scott presented Mr. Gibbings with a gold bracelet watch for Mrs. Gibbings on behalf of the British Westinghouse Co. He did not think the public had realised the value of the electricity works, or that by the establishment of this undertaking the Council had appropriated to itself the whole of the motive power of the city.

of the city.

Mr. J. C. Dove, the first chairman of the original Electric Lighting Committee, seconded the motion, which was supported by Mr. James Morton, one of the leading manufacturers of the city, and Dr. Overton, an ex-chairman of the Electricity Committee.

Castlewellan.—Street Lighting.—The Belfast News Letter says a further conference in regard to public electric lighting has been held, when a proposal by Mesers. Curran Bros. to supply and light 30 street lamps at £1 each per annum, provided the local people subscribe £500 in 6 per cent. preference shares was favourably received, and arrangements are to be made to give the necessary security. A generating station is to be erected.

China.—The China papers state, according to Eastern Engineering, that the Chefoo Electric Lighting Co. has commenced supplying current to consumers in Chefoo. The plant consists of two complete sets of 100-kw. alternators, consisting of two three-phase, 50-cycle, 3,300-volt alternators; two Belliss compound engines: three Babcock-Wilcox boilers; two Belliss jet condensers and pumps; two boiler-feed pumps, purifier and heater combined, and the necessary switchboard.

Clifden (Co. Galway).—PROV. ORDER.—The B. of T. has issued a provisional order, to be included in a confirmation Bill, authorising the Council to supply electrical energy in its administrative area.

Continental Note.—Germany.—As was expected, the Berlin City Council has resolved by a large majority to municipalise the works of the Berlin Electricity Works Co. on October 1st of this year, and has sanctioned a loan of £6,500,000 for this purpose. A scheme for the organisation of this department is to be submitted at an early date.

Cuba.—The following persons have been granted permission to install electric power and lighting plant in Cuba:—Senor Francisco Arredondo y Bentancourt, at Jobabo, in the municipal district of Victoria de las Tunas; Senor Dorindo Vazquez, in the town of Florida, province of Camaguey; and also Senor Perfecto Rodriguez, in the town of Florida. The Gacetas, which contain particulars regarding the installations to be carried out, may be consulted at the Commercial Intelligence Branch of the

Dublin.—COMMITTEE OF INQUIRY.—The Corporation has appointed a Special Committee to inquire into, and report upon, the administration of the electricity undertaking, the prices charged for light and power, the number of engineers and workmen employed, salaries and wages question and conditions, procedure in purchasing coal, and charge for interest on and repay ment of moneys borrowed.

Dundee,—The electricity department is running the risk of being seriously hampered on account of the large number of enlistments from the staff. Up to date there have been 72 enlistments, and other men are on the point of joining the Army. It was stated that Loohee sub-station has already been shut, and if more men go away further curtailment will be necessary. It is pointed out that the department may be unable to supply the foundries and jute establishments engaged in pressing Government work. The Committee has decided to ask the Government for an exemption for the staff still at work.

Edinburgh.—COAL CONTRACT.—A local paper states that the electricity department's coal contracts for the coming year have been settled, including some 25.500 tons for McDonald Road station, and 15,000 tons for Dawar Place station, bought at prices which represent an increased cost of £10,000 on the previous year.

Featherstone. — The U.D.C. has withdrawn its objections to the Bill of the Yorkshire Electric Power Co., and, in consequence, the district will be retained in the company's schedule.

Glasgow.—Showroom Proposals.—With reference to the proposal to open a permanent showroom for electrical appliances, to be equipped and managed entirely by the Corporation, on the lines mentioned in our issue of March 26th, page 459, agreement has now been reached, and the proposals submitted to the T.C. for approval. The original clauses in the proposal have been elightly modified, and the fourth paragraph now reads:—"That all fittings, accessories, lamps, and apparatus sold from the showroom shall be at the usual trade selling prices, such prices to be the usual current prices of the firms supplying goods to the showroom (originally list prices were mentioned). The fifth paragraph, which stated that, as far as possible, sales initiated in the showroom should be completed through the contractor, &c., has been deleted, and the seventh paragraph now states that the hiring of apparatus shall not be undertaken from the showroom "in the meantime," &c., the latter words having been inserted.

Haworth,—Prov. ORDER.—A prov. order for E.L. has been granted to the U.D.C.

Heywood. — PLANT EXTENSIONS. — The T.C. has approved of revised estimates, submitted by the electrical engineer for extensions as follows:—Buildings and plant, &o., £4,135; overhead mains and auxiliary plant, £2,600; total, £6,735.

Irlam.—Prov. Order.—The B. of T. has issued a prov. order authorising the Council to supply electricity for lighting and motive power purposes.

Itchen.—The U.D.C. has passed a resolution consenting to the prov. order for E.L. being applied for by the Southampton T.C. in respect of the parish of Bitterne, for which the laying of mains in a portion of Itchen is necessary, on condition that the mains to be laid will not affect in any way any of the rights of the U.D.C. under the E.L. order of 1913.

Kingstown.—The U.D.C. has appointed Mr. J. P. Tierney, of Dablin, as consulting engineer in connection with the electric lighting scheme for the district, at a fee of 5 per cent.—Freeman's Journal.

Liantarnam.—Proposed E.L.—The Highways Committee has had the question of E.L. referred to it, as the result of an offer from the South Wales E.L. and P. Co. to give a bulk supply.

London.—St. Pancras.—Life of Half-Watt Lamps.

—The Electricity Committee recommends that the electrical engineer be authorised to carry out the scheme submitted by him for the substitution of half-watt lamps for 172 open-type are lamps. The Committee reports that an experimental circuit of 14 half-watt lamps has been in operation for the past 10 months in George Street and Gower Street, and has proved successful. These lamps have burned for nearly 3,500 hours without a breakage, although only guaranteed for 800 hours. Taking as an estimate 2,000 hours' burning, the engineer estimates a saving of £132 per annum in maintenance charges; the estimated cost of the proposal is £500.

Loughborough.—The Corporation has, says the Sanitary Record, installed at its gas works a De Brouwer electric stoking plant and an electric coke conveying telpher.

Newcastle-under-Lyme.—The T.C. has been informed by the L.G.B. that the loan of £1,250 applied for for mains extensions cannot be granted. The Council had accepted the tender of Messrs. Callender, at £1.240, for the mains, and it was stated at a meeting on April 14th that the firm was prepared to adhere to this price, and to carry out the work when the war was

Newport.—A South Wales paper says that the proposal of the E.L. and Tramways Committee to increase the price of energy on account of increasing costs was adopted by the T.C.

Normanton.—Prov. Order.—The B. of T. has granted a prov. order authorising the Council to supply electrical energy for public and private purposes.

Oldham .- MILL DRIVING. - The Highfield Mill Co., North Moor, has decided to install electricity for driving purposes in substitution for steam driving.

-A CURIOUS COMPLAINT .-- Among those Rochdale.who complained to the Rochdale police in respect of the cutting off of the electricity supplies last Saturday was one gentleman who had a curious grievance. At the time the current was cut off, he explained, he had a large number of eggs in an incubator, and the shutting off of the warmth led to the eggs going cold and becoming

Rochester.—Refuse Destructor. — The T.C. has decided to inform the Chatham T.C. that it does not see its way to fall in with a suggestion that it should join in a scheme for the provision of a joint refuse destructor for the two boroughs.

Stanley (Yorkshire).—Prov. Order.--The B. of T. has granted a prov. order to the Electrical Distribution of Yorkshire, Ltd., authorising the latter to supply electrical energy for public and private purposes within the urban district.

Stockton Heath.—The P.C. has agreed to the terms of the Warrington Corporation relative to the proposed area of electricity supply, and to support the application provided certain clauses are included in the proposed Order.

tone. - Gas and Electricity Purchase. - The U.D.O. is, according to the Journal of Gas Lighting, considering the purchase of the local gas company's undertaking, which also embraces electricity supply, and has offered £35,000.

Sunderland.—WAR BONUSES.—At the T.C. on April 15th, several Committees proposed that a bonus be paid, the total involving £9,000 a year. In the case of the Electricity Committee, it was agreed that the bonus should be 3s. with wages up to 50s, a week, and in the case of the tramways 2s. up to 50s.

Swinton and Pendlebury.—Street Lighting, &c.-The U.D.C. has decided that from April 1st the price to be charged for electricity for street lighting be reduced from 13d. to 1 d. per unit.

During the past year the amount of energy generated at the electricity works was 351,116 units, an increase of 93,471 on last

- The T.C. having asked Truro. . - Е.L. Scheme. whether, in view of the refusal of a loan for carrying out the whether, in view of the relief of a loss for carrying out the E.L. scheme, it is tied by the stipulation that the compulsory works should be carried out within two years from the issue of the order, which period expires next August, the B. of T. has replied that it has no power to extend the time embodied in the order, which will remain in force notwithstanding any default in respect of compulsory works until it is revoked by it.

Tynemouth.—The Electricity Committee proposes to charge those consumers whose accounts are on a net basis, 5 per cent. extra for current supplied, and to return such additional 5 per cent. as discount, provided the account is paid with the ordinary period allowed for discount.

Waterford.—L.G.B. INQUIRY.—The date fixed for the inquiry into the Corporation's application for a loan of £30,000 for its electric lighting project is April 27th.

Wells (Somerset).—E.L. SCHEME.—At the monthly meeting of the City Council, a letter was read from the solicitors of the company which proposed to supply electricity to the city, stating that it had been decided, in view of the present national crisis, to withdraw the city of Wells from the proposed order.

West Hartlepool.—Proposed Loan.—Application is to be made for sanction to cover the necessary expenditure for extensions of mains and services for the use of customers, and for the purchase of a water softening apparatus.

# TRAMWAY and RAILWAY NOTES.

Aberdeen .- A demand for an increase in wages of 1d. per hour for employes earning 6½d. per hour and under, and of ½d. per hour for those in receipt of 7d. and over, has been made by the Aberdeen tramway men. The T.C. has offered a war bonus of 2s. to all with less than 30s. per week, the wages with bonus not to exceed 30s. per week.

-The L.G.B. has notified the Council that, in Barnes.view of the desire of the Treasury to restrict expenditure, it would not be able to authorise the loan for the purchase of electricallypropelled dust vans at the present time.

Birkenhead. — RATE RELIEF.—The Tramways Committee has decided to apply the sum of £1,260 to the relief of the rates. In previous years the available surplus has been transferred to the renewals fund, which at the close of the year amounted to £21,955. The Electricity Committee does not anticipate being able to afford any balance to the district rate.

Glasgow.—Female Conductors.—Everything points to an extension of the experiment with women as car conductors, to fill vacancies caused through shortage of male labour on the tramway system. The general manager, after reporting on the earlier observations made in the limited experiment with two the earlier observations made in the limited experiment with two women conductors, received sanction to extend the scope of the experiment for further information, and on Tuesday (April 13th) a special tuition-car was run over representative routes of the city and district system. The only passengers carried were eight women aspirants for the posts of conductors and an inspector, who initiated the ladies into the actual work of car conducting, including the selling and punching of tickets. According to the Telegraph, the manager has been instructed to engage as many additional women as conductors as may be required; the number is understood to be nearly 400, and a wage of 27s. a week, with uniform, is offered. is offered.

On Saturday the services of the eight women conductors enabled the department to run as many extra cars—the women conductors

week's holiday.

the department to run as many extra cars—the women conductors being left with the sole responsibility.

The Tramways Committee has remitted to the general manager for consideration and report, a letter on behalf of the Paisley District Tramways Co., intimating in connection with the renewal of the agreement for the running of the Glasgow Corporation cars from Hawkhead Road to Paisley Cross, that it could not agree to an allowance of 15 per cent. on the present rate per mile to meet working charges, and suggesting 10 per cent. as a sufficient allowance.

Heywood .- YEAR'S WORKING .- Subject to audit it is reported that the loss on the working of the Corporation tram-ways for the 12 months will amount to about £1,042, as compared with a profit a year ago of £85. The war is largely responsible for this adverse result.

-ELECTRIC 'Bus.-According to a Yorkshire paper, Ald. Meyer recently stated in the T.C. that an electric bus would be put on the Leeman Road for experimental purposes.

The question of the Hull Road tramways is under discussion in

view of a letter from the L.G.B. in regard to prospective expenditure.

The Corporation has had under consideration the situation created by shortage of men on the tramways. The drivers and conductors voluntarily agreed to work overtime to the extent of 12 hours a week if necessary, for the period of the war. They were willing also to work for double pay in lieu of taking their

Ilford.—The U.D.C., at a meeting last week, continued the debate on the motion of Councillor Bailey, that in view of the financial condition of the tramway undertaking, the best available expert advice be called in to assist the Council in formulating a expert advice be called in to assist the Council in formulating a scheme by which the undertaking can be placed upon a sound commercial basis. Replying to various criticisms, Councillor Bailey said that the Council had not accepted the manager's advice, and was apparently taking upon itself the responsibilities of experts. Had not the payment of £2,500 out of the reserve in relief of the rates been made some years ago, the reserve to-day would have been quite £10,000. After discussion an amendment was carried instructing the Tramways Committee to consider the advisability of obtaining expert advice to assist the Council advisability of obtaining expert advice to assist the Council,

Leeds .- YEAR'S WORKING .- The annual accounts of the tramways department for the year ended March 31st last, showed total receipts £433 939, as against £427,455 in the previous year. After deducting £115,601 for traffic expenses, £40,347 for general expenses, £43,609 for repairs and maintenance and £28,577 for power, the gross surplus to carry forward to not revenue account is £205,805, which compares with £201,073 for the previous year. The net surplus available for the relief of rates is £81,567, as compared with £70,004 last year.

London.—St. Pancras.—The L.C.C. has informed the B.O. that it is not prepared to accept its offer at the present time to supply energy to the Council's tramway department for the ensuing six summer months.

Manchester.—War Bonuses.—At a conference of tramway men on the 14th inst., the decision of the City Council to grant a war bonus of 2s. to all employés earning 30s. a week and under was discussed. It was decided to send a resolution to the under was discussed. It was decided to send a resolution to the Council, regretting that the recommendation of the employing Committee was not given a more favourable consideration. The recommendation of the Committee was that all employés earning

recommendation of the Committee was that all employes earning up to 40s, should receive the bonus.

RATE RELIEF.—At a meeting of the Manchester Tramways Committee, on Tuesday, it was agreed to give £100,000 in aid of the relief of the rates for the ensuing year. Prior to this result being announced, some doubt had existed as to whether the department would be able to keep up its contribution at last year's rate of £100,000—a figure to which it is pledged for a further year.

Musselburgh.—The T.C. has decided to insist upon the Musselburgh Electric Tramway Co. putting its track in better order, the burgh surveyor having reported that the track between Leretto and Levenhall was in a serious state of disrepair.

Newcastle.—The B. of T. having called upon the Cor-New Castle.—The B. of T. naving cancel upon the corporation Transways Committee to release as many men as possible in order that they may be employed on the manufacture of munitions of war, the situation was considered by the employes at a meeting on Sunday. It was decided to raise no objection, providing that the men who leave and go into the factories shall be guaranteed reinstatement at the end of the war, and that their work in the factories shall ocunt as transway service. The introduced to represent the factories shall be a provided. work in the factories shall count as tramway service. The intro-duction of women to fill their places was not objected to, provided that the women join the Union and are not underpaid. At a meeting of the T.C. on April 14th a deputation attended

from the tramwaymen and informed the Council that the ballot of the men had resulted in an almost unanimous rejection of the Council's war bonus offered at the last meeting. The Tramway

Committee is to report on the matter.

Radcliffe.—During the past year the Radcliffe tramways sustained a loss of £820.

Reading.-WAR BONUSES.-At the recommendation of the Tramways Committee, the T.C. has agreed that all employes of the tramways department, other than motormen and conductors, shall receive a war bonus of 3s. per week, or such part thereof as shall bring their wages to 34s.; motormen and conductors to receive a bonus of 6d. in addition to their increase of 2s. 6d.

Wigan.-WAR BONUSES.-As 25 per cent. of the men employed by the Tramways Committee of the Corporation would not benefit by the Council's war bonus scheme, application is being made by the local officials of the Tramway and Vehicle Workers' Association for a reconsideration of the claim of increased wage Failing this, the men ask for a war bonus of 2s. a week, for all employes over 21 years of age, and 1s. per week for those under the age.

# TELEGRAPH and TELEPHONE NOTES.

Canada.—The annual report of the Marconi Wireless Telegraph Co. of Canada states that the company now operates, in all, 40 stations in the Dominion, in Newfoundland, and in Labrador. Ninety-three steamers of Canadian register are equipped with the Marconi system. With the completion of the duplex system the Louisberg trans-Atlantic receiving station has been brought into operation, in addition to the installation of high-speed transmission at Glace Bay.

Telephone Progress.—The Telegraph and Telephone Journal for April points out that while in Germany the number of telephone subscribers has greatly decreased, in this country the number increased by nearly 5,000 during the latter half of 1914, in spite of the disconnection of lines rented by alien enemies. In addition some 4,000 military and naval stations were connected, which are not included in the table given below:—

United States.—The accumulated traffic at the Tuckerton. N.J., wireless station has been cleared up, and messages for Germany and Austria-Hungary are being accepted, subject to the former restrictions, including liability to considerable celay.

# CONTRACTS OPEN and CLOSED.

-June 2nd. Electric lighting Australia. - Melbourne. -Australia.—Melbourne.—June 2nd. Electric lighting material for cars (Contract 28.187). Tender box, Railway Offices, Melbourne. Particulars at Contractors' Room, Spencer Street.* Deposit ½ per cent. of amount of tender.

June 1str—Deputy P.M.G. Eight miles of paper-insulated lead-covered cable. (Schedule No. 1,184.)*

June 2nd. Bogie trucks, wheels and axles for 10 cars of the St. Kilda-Brighton electric street railway (No. 28,621) for the Victorian Railway Commissioners.*

June 15th. City Council. Four mechanically-fired boilers, one turbing-driven boilers, early lating.

June 15th. City Council. Four mechanically-fired boilers, one turbine-driven boiler-feed pump, two fuel economisers, circulating water pumps. City Electrical Engineer. Specifications from Mesars. McIlwraith. McEacharn & Co., Ltd., London, E.C. Queensland.—June 1st (instead of March 16th). P.M.G. Switchboard for Warwick. See "Official Notices" March 26th. Sydnky.—May 31st. Three electric battery locomotives for Public Abattoirs, Homebush, for the Department of Public Works. Specifications, &c., 5s., from the Accountant, Public Works Department.

June 16th,-Daputy P.M.G 400 Morse sounders, American pony pattern. (Schedule No. 419.)

Specifications for the items marked can be seen at the B. of T. Commercial Intelligence Branch in London,

Aldershot. — May 4th. Steam and other pipework; water-softening plant. See "Official Notices" March 26th.

Dundee. — April 28th. Corporation. Centrifugal circulating pumps, and 750 ft. of 42-in. and 30-in. cast-iron pipes. See "Official Notices" April 9th.

Hendon.—The Guardians are inviting tenders for an electric lighting installation for the workhouse.

London.—Wandsworth.—April 28th. Three months' supply of electrical fittings, &c., for the B. of G. Forms of tender from Mr. F. J. Curtis, Clerk, Union Offices, St. John's Hill, S.W.

Mountain Ash. - April 26th. U.D.C. Sub-station building, E.H.T. underground cables, L.T. overhead lines and public lighting, E.H.T. switchgear, L.T. switchgear and transformers, for Aberoynon. See "Official Notices" April 16th.

New Zealand.—Wellington.—Extension of date to May 21st. Public Works Office. A three-unit exciter set (Section 49) and a 1,500-kw. generator (Section 50), for Lake Coleridge power scheme. Specifications and forms of tender may be consulted at the office of the High Commissioner in London for New Zealand, 13, Victoria Street, S.W., and at the Board of Trade Commercial Intelligence Branch in London.

South Africa.—JOHANNESBURG.—June 1st. Municipal Council. 24 double-pole, automatic, oil-immersed circuit breakers of a continuous carrying capacity of 200 amperes (Contract No. 971). Specifications, &c., from the Controller of Stores, Municipal Offices, Plein Square, Johannesburg. Tenders to Town Clerk,—Board of Trade Journal,

Spain.—Tenders have lately been invited by the municipal

authorities of Noblejas (Province of Toledo) for the concession for the electric lighting of the town during a period of five years.

The municipal authorities of Z shinos (Province of Badajos) have lately invited tenders for the concession for the electric lighting of the town during a period of five years.

Tasmania. - Launceston. - July 26th. Sub-station equipment. Section I, Converter machine, switchgear, &c.; Section II., Underground feeder cable. Specification (21s.) from the City Electrical Engineer, Town Hall.

# THE POWER SUPPLY OF THE CENTRAL MINING-RAND MINES GROUP.

AFTER briefly outlining the contents of his paper on the above-named subject at the Institution of Electrical ENGINEERS on Thursday last week, MR. J. H. RIDER, M.I.E.E., described the sequence of operations in the gold mining industry with the aid of a number of lantern slides, most of which, thanks to his courtesy, we are enabled to reproduce herewith. The group of mines with which the author has been associated as consulting electrical and mechanical engineer for the past four years crush about

 $8\frac{1}{2}$  million tons of ore per annum, and produce about 36 per cent. of the total gold output of the Transvaal, or one-seventh of the total gold output of the world. When it was decided, in 1908, that the whole of the power requirements of these mines should be taken from an outside source, a separate supply company, called the Rand Mines Power Supply Co., Ltd., was formed for that purpose. This power com-pany owns the Rosherville and Vereeniging power stations, and the air-compressing station at Robinson

Central Deep (a section of Crown Mines, Ltd.).* During recent years electrical power has been adopted for almost all the mechanical operations except rock-drilling, which is done with compressed air mainly supplied from central stations, and, in some cases, the air is compressed by electrically-driven plant; thus the horse-power of the 1,500 motors employed amounts to 142,300 H.P., and the annual

air system is 37,900 kw., and the load factor 34 per cent.; the consumption is 103 million "air units" per annum, the air unit representing 0.641 of the energy in one electrical unit.

The most important service is that of winding, as not only is the output of the mines entirely dependent upon it, but also the safety of thousands of men (both white and coloured) who descend and ascend the shafts daily. There are at the present time 38 shafts in use on the mines of the

group, many of which have underground winders for the lower depths, in addition to surface winders. One of the largest of the latter is illustrated in fig. 2.

Fig. 3 shows the headgear

of the City Deep Mine, with three hoists; the rock excavated at a depth of over 3,000 ft., when raised to the surface, is tipped into bins over the "grizzlies" seen in the foreground, and is then fed upon broad rubber travelling sorting belts. The function of the grizzlies is to permit the small stuff to fall through, while the large

lamps roll over the bars, thus roughly sorting the material in the first instance. Some of the sorting belts are seen in fig. 4; they travel very slowly, and Kaffir "boys" standing alongside pick out the useless rock, which is easily distinguished from gold-bearing ore. The latter passes on to the crushers, which reduce it to pieces not exceeding 11 in. in diameter. The crushers, shown in fig. 5, are

FIG. 1.-CITY DEEP MINES: GENERAL VIEW.

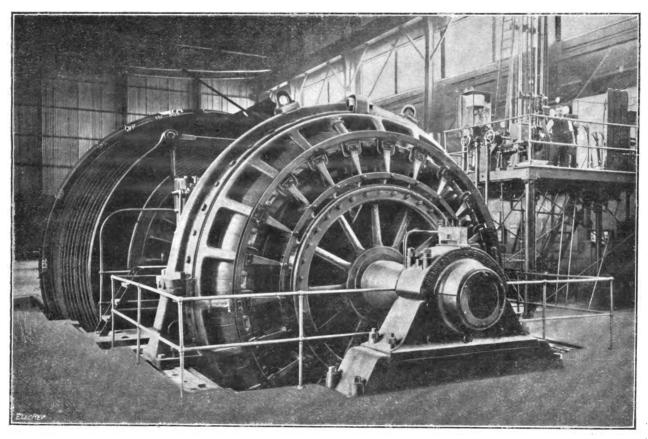

FIG. 2.—WINDER DRIVEN BY TWO 2,000-H.P. D.C. MOTORS, AT SOUTH RAND SHAFT, CROWN MINES, LTD.

consumption of electrical energy to 310 million units, the maximum demand being 47,300 kw. and the load factor 75 per cent. The maximum demand upon the compressed-

For a description of these stations, see FLECTRICAL REVIEW, Ma-ch 28tb, 1913,

driven directly by electric motors, and owing to their heavy duty give rise to severe vibration; for this reason, as will be seen in the view, their axes are placed at right angles, to distribute the vibration over the whole building. motors driving the crushers are shown in fig. 6.

In the long run, the ore has to be reduced to an impalp-

able powder, in order to enable the whole of the particles of gold to be extracted. The next process through which it passes for this purpose is illustrated in fig. 7, which shows the upper portion of a battery of stamp. These are steel rods shod with stamps at the lower ends, weighing 1,200 to 2,000 lb., and provided with tappets higher up, which, as shown, are lifted by cams mounted on a rotating shaft. The cams are double, so that each rod is lifted and dropped twice in a revolution, and they are arranged so

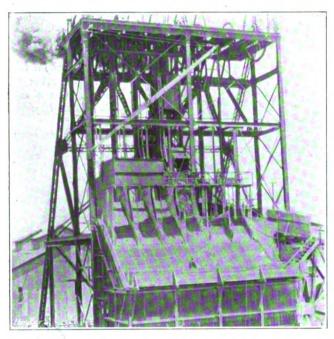

FIG. 3.—HEADGEAR AND GRIZZLIES: CITY DEEP.

that the stamps operate consecutively. A very brief period elapses between the dropping of a stamp, which of course occapies a constant interval under gravity, and its next lifting by the following cam; hence, as Mr. Rider pointed out, a slight increase in the frequency of the alternating-current supply to the driving motors involves a serious risk of "camming," that is, receiving the blow of the stamp on the following cam, with disistrous consequences to the latter. Experience has shown that this danger exists at a speed greater than 98 drops per minute, and it increases with any increase in the speed of dropping.

Having fixed the output of the stamp mill on the basis of 98 drops per minute for each working stamp, while any

FIG. 4.—SORTING BELTS: CITY DEEP.

increase in the speed is dangerous, any decrease will reduce the output of the mill in the same proportion. As the variation of frequency permitted by the contract with the supply company is 5 per cent. up or down, this has to be taken into account in settling the speed of the driving shaft. During the early period of the power supply considerable trouble was experienced from these causes, which affected all the mills at the same time. As it was afterwards found that the supply was more generally given at or near the higher frequency, the drives were altered to suit, this being the lesser evil.

At this stage water is employed to wash the crushed rock through screens of small mesh, and the mixture passes on to tube mills (fig. 8), in which it is finally reduced to pulp. The tube mill is a cylindrical steel vessel, like a boiler shell, a common size being about 22 ft. long × 5 ft. 6 in. diameter. It is carried upon hollow trunnions, and is rotated at a speed of about 28 R.P.M. The interior is lined either with hard segmental stone blocks or with concrete in which steel pins are embedded. The crushed ore as it comes from the stamp mill in the form of a coarse pulp is fed through the trunnion at one end, together with a number of small selected pieces of ore, called pebble, about 3 in. cube, which act as grinders, and themselves gradually become reduced to powder. The finished product comes

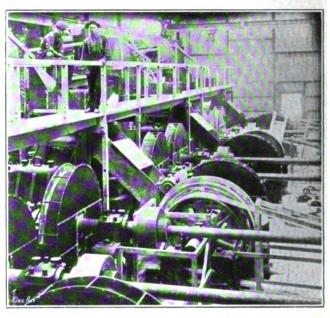

FIG. 5.—CRUSHERS: CITY DEEP.

out of the trunnion at the other end, and is then ready for passing over the amalgam tables.

In fig. 9 are shown motors driving tube mills directly through Citroen spur gearing, with the controlling apparatus on the opposite side of the motor room. The gear ratio, however, was too great for single-reduction gearing to cope with satisfactorily, and in later practice the motors drive countershafts by belt, as shown in fig. 10. The tube mills have a certain amount of end play, so that the gearing should have straight teeth.

The next process is the extraction of the gold, in which

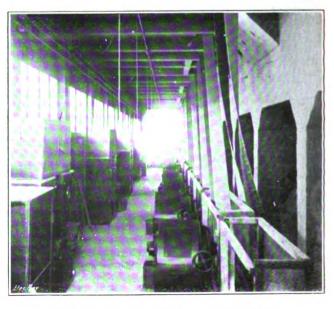

FIG 6.—CRUSHER MOTORS: SOUTH RAND.

electricity plays but a small part. The pulp passes over a series of copper tables, shown on the left of fig. 11, the upper surface of which is amalgamated with mercury, and here the greater part

of the gold is trapped. Periodically the amalgam is scraped off, and the gold recovered by vaporising the mercury. The pulp, after passing over the mercury tables, is further treated by the cyanide process in the large tanks shown in fig. 1, to remove the remaining gold as far as possible. The cyanide solution is then carried to the boxes shown on the right hand of fig. 11, where the residue of the gold is precipitated on zinc shavings. The product is then smelted and the gold recovered.

Winding from deep levels on the mines of the group is effected mainly by three-phase induction motors, but in some

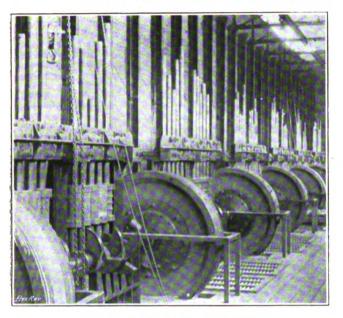

FIG. 7.-STAMP MILL: CITY DEEP.

cases DC. motors are used on the Ward-Leonard system. The former are controlled by variable rotor resistances, usually of the liquid type, as shown in fig. 13. The electrodes are in the upper tank, and the electrolyte is pumped up by a centrifugal pump, which determines the rate of rise of level, and therefore the acceleration of the motor, in lependently of the driver. Various troubles have been met with, and successfully overcome, in the operation of these liquid resistances. More recently electrically-operated

FIG. 8.-TUBE MILLS: CITY DEEP.

contactor switches have been used in conjunction with metallic resistances, and have given very satisfactory results.

The D.C. motors are controlled by metallic resistances in the field circuit of the generator. One of the latter winders is illustrated in fig. 2, p. 585; this is the largest electric winder in South Africa, and is driven by two motors, each of 2,000 H.P. There are two cylindro-conical drums, each 22 ft. in diameter, which run at 54 R.P.M. and wind a net load of 16,000 lb. from a depth of 3,540 ft. at a speed of There are three of these winders at 3,500 ft. a minute. the South Rand shaft of Crown Mines, Ltd. The motorgenerator for the set illustrated runs at 350 R.P.M., and has

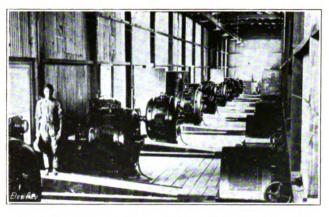

Fig. 9.—Tube Mill Motors (Single-Reduction Drive): City Deep.

two generators, working at 500 volts, which are connected in series with one another and with the two winding motors. The current taking at starting is frequently 5,000 amperes. The electrical equipment was made by the General Electric Co., U.S.A.

While most of the compressed air is supplied by the power

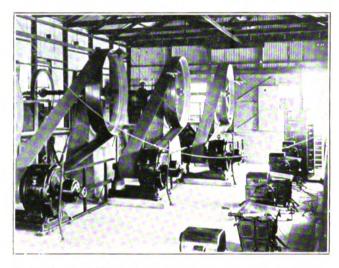

FIG 10.—Tube Mill Motors (driving through Counter-shaft): Nourse,

company, four of the mines have their own compressing plant. Fig. 14 shows two vertical two-stage air compressors made by Messrs. Belliss & Morcom, Ltd., and driven by electric motors. In some cases existing steam-driven air-compressors

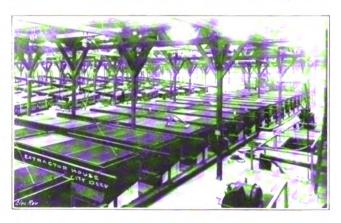

FIG. 11.—EXTRACTOR HOUSE: CITY DEEP.

have been converted, by grooving the fly-wheel rim for ropes and substituting a motor for the engine (fig. 16).

A direct-coupled compressor at Bantjes is of the highspeed turbine type. It compresses the air up to 7.5 lb. gauge pressure, at which pressure the horizontal rope-driven compressors take it and complete the compression. It was made by Messrs. C. A. Parsons & Co., and has been most successful in operation.

The driving is by three-phase constant-speed motors, and

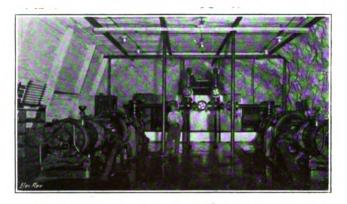

FIG. 12.—UNDERGROUND PUMP CHAMBER: D. ROODEPOORT DEEP.

the governing is done by butterfly valves in the main suction

pipes, which are controlled by the air pressure, and close as long as the pressure in the receiver is above the normal. As soon as the pressure falls the valves open and the compressors work normally.

The system of pumping water from the mines with Cornish pumps in stages of about 500 ft. has been superseded with great advantage by the plan of allowing all the water to gravitate to the lowest level and pumping it to the surface in a single lift. For this purpose motor-driven geared ram pumps were used until 1912, when it was decided to use high-speed multi-stage centrifugal pumps, with direct-coupled motors, at the South Rand shaft of the Crown Mines, Ltd., and at No. 1 shaft, Durban Rood-poort Deep, Ltd. The plant at both mines is identical, and each consists at present of two pumping units.

One of the underground pump rooms is shown in fig. 12; each unit consists of a high and low-pressure Sulzer pump, with the motor between them, and lifts 375 gallons per minute to a

lifts 375 gallons per minute to a height of 2,400 ft. The sets run at 1,470 R.P.M., and take about 500 B.H.P. Sets of twice the size are being installed at Crown Mines. The saving in running cost was sufficient to wipe out the whole of the capital outlay in two years. It is not that the centrifugal pump, by itself, has a higher efficiency than the ram pump, but the

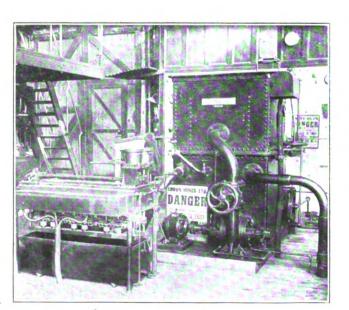

FIG. 13.—THREE-PHASE CONTROL TANK: CROWN MINE.

use of the former renders concentration of large, high-power and high-speed pumping units possible in a minimum of space, with a minimum of attention and very low maintenance costs.

The success of the centrifugal pumping system has been such that large similar schemes are now being considered for other mines of the group.

The power company's electric supply is given at normal pressures of 2,100 volts and 525 volts at the consumers' terminals. Fig. 15 is a view of a switchboard in one of the switch-houses; it is of the cubicle type, built of reinforced concrete, the high-pressure gear being on one side of the switch-house and the low-pressure on the other. Owing to troubles resulting from installing switches rated merely for the full load of the circuits, the author made a rule that all oil-switches in a switch-house should be of the same size, rated for a current of 800 amperes at 15,000 volts, whether used on 2,100-volt or 525-volt circuits, with the result that trouble in switch-houses has practically disappeared.

Three-core, lead-covered and armoured cables, laid in trenches, are universally used between the main switch-house and the various sub-distribution points on each mine. The points are arranged to suit the local conditions, and

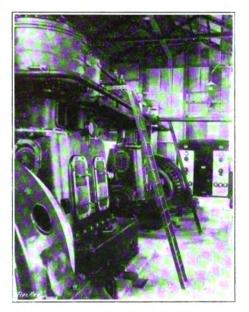

FIG. 14.—AIR COMPRESSORS AND SWITCH-BOAND: D.R. DEEP.

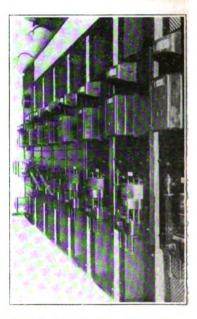

FIG. 15.—SWITCHGEAR IN SWITCH-HOUSE: D.R. DEEP.

are generally interconnected, so that the failure of any main cable does not stop the supply. Link cages, without switches, are provided at the sub-points, so that the sub-circuits can be isolated at any time and the feeders interconnected as may be required.

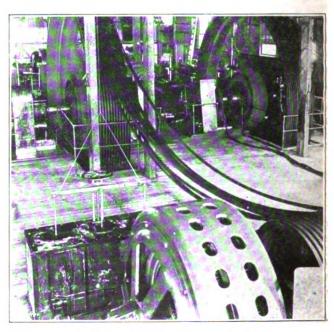

FIG. 16.—ROPE-DRIVEN COMPRESSORS: BANTJES,

### CONTRACTS CLOSED.

(Continued from page 584.)

Aberdeen.-Mr. Thomson has secured the contract for the electrical installation at the City Hospital extension.

Belfast.—The Corporation Tramways Department has placed a contract with Messre. Siemens Bros. Dynamo Works, Ltd., for carbon filament lamps for twelve months.

Bristol.—The T.C. Dooks Committee has accepted the tender of Mesers. W. T. Henley's Telegraph Works Co. for 47 coils of vulcanised I.B. cable, of various sizes.

Colchester.—The T.C. has accepted the following tenders for supplies to the electricity works:—

Stamford & Co., Bagshaw.—Coal elevator, 289.
Pope's Lamp Co.—Metallic-filament lamps,
Joslins, Ltd.—Prepayment installations.
Lucy & Co.—Fuse-boxes.
Patsley Engineering Co.—Castings.
Williams & Co.—Electrical accessories, oils, &c.

Edinburgh. — The Corporation E.L. Committee has settled the coal contract for the coming year at about 4s. 6d, a ton more than was paid last year. The coal bill for next year is increased by £10,000.

Halifax.—The Corporation Electricity Department has placed a contract for 10, 25, and 50-amp. D.P. ironclad switches, required during the next 12 months, with Mesers. J. H. Tucker and Co. The Tramways Department has placed a contract for lampholders, switches, &c., for the same period, with the same firm.

-The U.D.C. has accepted the tender of Hampton.-Messra. Stuart & Moore for fire alarms in Station Road, at £18 12s., with 80s. per annum for maintenance.

Ilford.—The following tenders have been accepted by the U.D.C. for annual supplies to the Tramways Department :-

Messrs. Wiseman.—Trolley heads and harps.
British Westinghouse Co.—Armature coils.
Le Carbone, Ltd.—Carbon brushes.
Scholey & Co., Ltd., and British Thomson-Houston Co.—Pinlons and gear wheels.

wheels.

John Brown & Co.—Tires, steel, and special steel.

John Brown & Co.—Tires, steel, and special steel.

B.I. & Helsby Cables, Ltd.—P. & S. substitute tape, and Para tape.

L. Andrews & Co.—Blackley tape.

F. Smith.—Piaso wire.

Duesek Bros. & Co.—Graphite grease.

A. B. Gross & Co.—Motor grease.

Joalins, Ltd.—Oil.

R. Kearsley & Co.—Varnishes.

Lichfield.—The T.C. has accepted the tender of Messrs. Clive & Co. for alterations to the telephone service in connection with the electric fire alarms, and the provision of poles, relay ball, insulatore, lines, &c.

London.—BERMONDSEY. — The undermentioned purchases of coal have been made by the Electricity Committee: chases of coal have been made by the Electricity Committee:—C. Tucker & Co., 10 tons wharf small, 22a, 3d. per ton: Charringtons, 16 tons nutty slack, 25s.; W. Moore & Co., 10 tons wharf small, 21s.; Thorpe, Head & Co., 20 tons wharf small, 20a.; Myers, Rose & Co., 100 tons Stanley slack, 18s. 9d.; Bradbury & Co., 30 tons nutty slack, 23a, 6d.; Thorpe, Head & Co., 60 tons nutty slack, 20s.; Dinham, Fawcus & Co., 100 tons West Hallam nuts, 25s.; 100 tons, Sharlston pea slack, 25a.; 100 tons West Hallam nuts, 25s. The Committee recommends the Council to continue, for a further period of two months, to pay Bradbury, Son & Co., Ltd., the increased charge of 1s. 6d. per ton on the coal contract.

Meter Contracts, &c .- The Swindon and West Hartle-Meter Co. Ltd., for the supply of Bastian meters, of from 3 to 10 amperes and 2½ to 5 amperes respectively.

The Electrical Apparatus Co., Ltd., has obtained a contract from the Dundalk U.D.C. for the supply of house service meters for the year ending March 31st, 1916.

Messrs. J. H. Tucker & Co. have recently received contracts for annual supplies of service fuse-boxes from Hford U.D. Council, Bolton and Blackburn Corporations; for lampholders from Swindon Corporation; and for ironolad switches from Dundalk U.D. Council.

sers. Chamberlain & Hookham, Ltd., have received contracts Mee

from the following towns for the supply of meters for 12 months:— Kirkcaldy, West Hartlepool, Swindon and Pontypridd. The British Westinghouse Electric and Manufacturing Co., Ltd., have recently received contracts from the following supply authorities for single-phase A.C. house service watt-hour meters:— Bath Corporation; Beckenham Urban District Council; Blackburn Corporation; Bristol Corporation; Croydon Corporation; Ecoles Corporation; Ipswich Corporation; Leeds Corporation: Rhondda Urban District Council; Watford Urban District Council; West Ham Corporation.

Southampton.—The Borough Insurance Committee has accepted the tender of Mesers. H. C. Taplin & Sons for the E.L. installation at the Committee's offices,

Sunderland. — CORRECTION.—In last week's issue, "C.O. two recorders" was, of course, a printer's error for "CO2 recorder.

Thames Ditton.—The U.D.C. has accepted the tender of Meesrs. Stuart & Moore for electric fire alarms at Claygate, at £82 9a

Windsor.—The T.C. has accepted the tender of the Windsor Electrical Installation Co., Ltd., for the electric light installation at the waterworks and house with 54 lights, at £64, with £22 for an extra lighting main.

## FORTHCOMING EVENTS.

Junior Institution of Engineers.—Friday, April 23rd. At 8 pm. At 89, Victoria Street, S.W. Paper on "The Developments of the Mavy," by Mr. E. W. Hobbs.

Physical Society of London.—Friday, April 28rd. At 5 p.m. At the Imperial College of Bolence, South Kensington. Paper on "The Self-Induction of Solenoids of Appreciable Winding Depth," by Mr. S. Butterworth.

National Association of Colliery Managers and Association of Mining Electrical Engineers. Saturday, April 24th. At University College, Nottingham. Joint meeting. Paper on "Protective Devices against Lightning and Surges," by Messra. E. Kilburn Scott and L. F. Fogarty.

Association of Mining Electrical Engineers (Lancashire, Cheshire, and North Staffordshire Branch) and North Staffs. Branch of the Colliery Managers' Association.—Saturday, April Mth. At 8 80 p.m. At Technical College, Stoke. Paper on "Colliery Electric Lighting," by Mr. G. S. Corlett.

Hiuminating Engineering Society.—Tuesday, April 27th. At 8 p.m. At the House of the Royal Society of Arts, John Street, Adelphi. Discussion on "Visibility: its Practical Aspects," opened by Messrs. C. C. Paterson and B. P. Dudding.

Institution of Civil Engineers.—Tuesday, April 27th. At 8 p.m. At Great George Street, S.W. Annual General Meeting.

Association of Supervising Electricians.—Tuesday, April 97th. At 8 p.m. At Mt. Bride Institute, Bride Lane, E.C. Paper on "Lightning Conductors," by Mr. H. C. Hands.

Dynamicables. - Wednesday, April 28th. At Trocadero Restaurant. Anniversary Meeting and Dinner.

Royal Society of Arts.—Wednesday, April 28th. At 8 p.m. At John street, Adelphi, W.C. Paper on "The Utilisation of Solar Energy," by Mr. A. S. E. Ackermann.

Institution of Electrical Engineers.—Thursday April 29th. At Victoria Embankment, W.C. Paper on the "Bombay Hydro-Electric Scheme," Embankment, W.C. by Mr. A. Dickinson.

(Manchester Local Section).—Tuesday, April 27th. At Engineers' Club, 17, Albert square. At 7 p.m. Annual General Meeting. At 7.80 p.m. Mr. Dickinson's paper, as above.

(Students' Section),—The Annual General Meeting has been post-poned from April 28th to May 5th.

Royal Institution of Great Britain,—Saturday, May 1st. At 8 p.m. At Albemarie street, W. Lecture (1) on "Photo-Electricity," by Prof. J. A. Fleming, F.R.S. At 5 p.m. Annual Meeting.

### NOTES.

Institution and Lecture Notes.—Iron and Steel Institution and Lecture Notes.—Iron and Steel Institute.—The annual meeting will be held at the Institution of Civil Engineers at Westminster, on May 13th and 14th. In the event of Mr. Greiner being unable to attend, Mr. Arthur Cooper, Lt.D. (immediate past-president), will preside. The Beesemer Gold Medal for 1915, which has been awarded to Mr. Pierre Martin (formerly of Sireuil, near Paris), will be received on his behalf by his Excellency M. Paul Cambon, the French Ambassador, who has consented to attend. Prof. Hubert (Liége University) is to deliver an afternoon lecture on "Large Gas Engines." In the programme of expected papers there is one by Messrs, A. M. Portevin and E. L. Dupuy, on "Thermo-Electric Properties of Special Steels." On account of the war the annual dinner will not be held. It is provisionally settled that the autumn meeting will be held in London visionally settled that the autumn meeting will be held in London

during the week ending September 25th.

Institution of Electrical Engineers.—The annual general meeting of the STUDENTS' SECTION has been postponed from April 28th to May 5th, at 7.45 p.m., when Sir John Snell will give

an address.

Royal Society of Arts.—On Wednesday last week, Mr. T. Thorne Baker read a paper on "The Industrial Uses of Radium," dealing mainly with the application of the residues of radium factories to agricultural purposes. He stated that the a-rays produced increased vitality and quicker germination of seeds, and that radium emanation accelerated the growth of plants. Salts containing exceedingly small quantities of radium had been used for the treatment of rheumatism with highly satisfactory results, and radium could be used to clot milk in place of rennet. The use of radium to render watch hands luminous in the dark was also described. described.

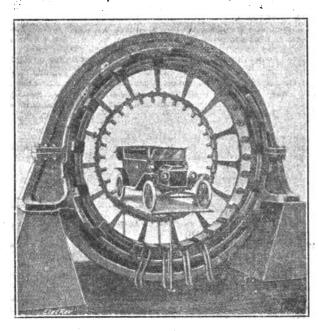

The Government and War Munitions.—From a notice which appears in our advertising pages to-day, it will be seen that firms engaged on the manufacture of armament and munitions of war and requiring additional machinery, are requested to communicate with Mr. George M. Booth, Room 367, War Office, Whitehall, S.W., giving particulars.

Educational Note. — CRYSTAL PALACE SCHOOL OF PRACTICAL ENGINEERING.—The new course will commence on Wednesday, April 28th, See our advertisement pages to-day.

Large D.C. Generator.—Four large direct-current generators are now being installed in the Detroit plant of the Ford Motor Co. by the Crocker-Wheeler Co., Ampere, N.J. Each of these machines will be directly connected to a two-cylinder tandem gas engine and a compound condensing steam engine.

The maximum diameter of the generator shaft is 34 in.; it is 26 ft. long, and weighs approximately 35 tons. The greatest diameter of the armature is 15 ft. 10 in., and its total weight is 42 5 tons. The armature spider is of cast-iron, and is cast in two parte, each part weighing about 9 tons. Eight bolts are used to hold the spider halves together, each bolt weighing 500 lb., and each fluted nut, of which there are 16, weighing 90 lb. In order to obtain the proper tension on the bolts, each bolt was heated before being placed in position, so that on cooling after the nuts had been tightened the bolt contracted and drew the two halves of the spider together with great force. The laminated core consists of 26,000 separate parts, each part having to be handled separately during the process of assembling. There are 10,000

FRAME OF DIRECT-CURRENT GENERATOR FOR FORD PLANT.

core laminations and 5,600 core ventilators. The commutator is made up of 630 copper bars insulated from each other and assembled on a cast-iron spider frame. This spider frame is also made in two parts, each weighing 5,000 lb. The diameter of the commutator over the bars is 9 ft. 2 in., and its total weight is 10 tons, of which 4 tons is copper. The completed armature mounted on the shaft is supported on two bearings, each being 33 in. in diameter and 5 ft. long.

The magnet frame is of cast-iron and has a section resembling

The magnet frame is of cast-iron and has a section resembling an enlarged T-rail section. Like the other large castings, it was cast in two parts, each weighing 20 tons. The outside diameter of the frame is 23 ft. 2 in., and the distance across the base 25 ft. 8 in. Thirty main poles and 30 interpoles were bolted to the inside of the frame after the field coils were in place. The rocker ring to which the brush-holders are fastened is supported by brackets cast on the side of the magnet frame. The rocker ring is of cast-iron, and has an outside diameter of 20 ft. It weighs 4 tons. The machine is equipped with 240 brushes.

and has an outside diameter of 20 ft. It weighs 4 tons. The machine is equipped with 240 brushes.

The total weight of the generator, including the shaft, is about 135 tons of which 13 tons is copper. At 250 volts the generator is rated at 15,000 amperes. The normal rating of the machine is 3,750 kW., and the maximum rating is 4,500 kW. The generator operates at a speed of 80 R.P.M., which gives a peripheral velocity of the armature of about a mile a minute. It was necessary to split the large castings in order to meet railroad-tunnel clearances.—

Electrical World.

Electricity in the Roumanian Petroleum Industry.—Important modifications have recently been introduced in the rules governing the use of electricity in the Roumanian petroleum industry. A resume of the revised regulations follows, and deserves the notice of manufacturers concerned, since Roumania is one of the fields in which advantage may be taken of German paralysis to extend our own trade. Squirrel cage motors are ill adapted, by reason of their high and invariable speed, to the requirements of the petroleum industry, hence the rule prescribing the use of these machines has been considerably broadened. Step-down transformer stations fed at 1,000 volts, or higher pressure, and all generating stations must be at least as far from any boring as the distances prescribed for boilers and forges in collieries. Where there are no spouting wells, transformers in gas-tight chambers are excepted from this rule. Transformers working at 1,000 volts or lower pressure, and supplying lighting current, are permissible near the well if they and their fuses and switchgear are oil-immersed. In the immediate neighbourhood of the well, one and the same cable must be used for lighting and motor branches must be located in the motor room and accessible only to authorised

persons. Lighting generators or transformers at the well-head must be in fireproof buildings, accessible only to authorized persons. In no case is more than 1,000 volts P.D. permissible between conductors in a sinking. High-pressure circuit-breakers isolating sinkings may be mounted on the poles, if oil-immersed: other switches or fuses may not be so mounted. Lightning conductors with spark gaps are forbidden. An oil-immersed isolating switch must be provided in each well network for use in case of fire. Single-pole switches are forbidden; multipole switches must be mechanically coupled. Telegraph, telephone and signalling apparatus must produce no open sparking, and must incorporate devices safeguarding possible contact of their wires with high-pressure leads. Only hermetically-sealed glow lamps with armoured protecting globes are permitted in the workings, and in the latter the use of direct-current motors is forbidden. Short-circuited induction motors of the squirrel-cage type should be used whenever possible in the workings. Slip-ring motors are permissible so long as all sparking parts are enclosed in a chamber which is sealed automatically and hermetically. An official certificate is required as to the safety of the motor in a gas-filled space and as to the maximum temperature rise of the controlling resistances. Switchgear or other apparatus capable of producing a spark in the motor room must be oil-immersed, unless the casing is hermetically sealed, and excepting lighting fuses up to 10 amperes capacity. Owners are bound to employ at least one qualified electrician certificated by the authorities; this electrician and the works manager are responsible for the proper erection and operation of the installation. Only equipment sanctioned by the Minister of Commerce and Industry may be installed, hence care should be taken that all necessary formalities are concluded before delivery is made or special expenditure incurred. Full particulars, plans and specifications of proposed equipment should be laid befor

Telephony and Telegraphy in the Field of War.—A graphic account of field telegraph and telephone work has been contributed to a Frankfort newspaper by a correspondent who, on the occasion of his presence with the army commanded by the Crown Prince of Bavaria, had an opportunity of inspecting the entire telegraph and telephone system of this particular army in the western area of operations. The exchange for the whole of the traffic was located in a large private house; it was equipped within three weeks, had 95 direct lines and established about 5,000 connections daily. In order to carry out the work, which comprised lines of a total length of 740 miles, 300 men of the First Bavarian Telegraph Battalion were available, and these were able to lay 54 lines in a single day immediately after the exchange was finished. The difficulty of executing the works was increased by the circumstance that French apparatus was employed for the greater part, and this had to be altered to correspond with German requirements and custom, the apparatus being found in French Post Offices. It was also possible to use the French network to some extent, although it was largely destroyed. Notwithstanding all the difficulties the exchange was soon completed, and a network of communication was provided which had direct lines right down to the divisions and rendered possible direct communication with the grand army headquarters and the neighbouring armies.

Each Army corps can be reached by means of five different lines, and from these the divisions can each be called by at least two different lines. Lines from the divisions then lead to the brigades and regiments, and the terminal line proceeds to the trenches, from which every battalion, and, in many cases, every company has a connection to the rear. To these means of communication are added the numerous lines necessary for the artillery, artillery observers in the trenches, &c.

Communication with neighbouring armies is effected by means

Communication with neighbouring armies is effected by means of two direct lines in each case, whilst two similar lines maintain connection with the grand headquarters. In addition each army corps is connected by direct lines with its neighbouring corps, and each division with its adjoining division. It has frequently been necessary to carry out repairs necessitated by storms, and besides there has to be taken into consideration the much endangered situation of the telephone stations in places where they must be maintained for military reasons, and where they lie within the range of hostile artillery fire. Stations indeed exist which are continuously fired at, and security has to be sought in deep cellars which are made bomb-proof as far as possible. Many lines are shot down, and the places of interruption have to be discovered and the necessary repairs promptly made to maintain communication. The telegraph traffic is effected in this army as at the grand headquarters by the use of the French Hughes apparatus, and the daily work ranges from 900 to 1,000 service telegrams, thus almost, if not entirely, excluding any private messages.

cluding any private messages.

A number of portable stations for wireless telegraphy are also associated with the army. These stations, which are partly hauled by horses and partly by motor cars, have a quiet period in times of fighting for positions, but a great strain is imposed upon them when movements are taking place. The range of the stations is a few hundred kilometres. The lines of the army chief command are connected to the rear with those of the service corps, which are worked by the telegraph service corps, and are then joined further to the rear with those of the general government, which are operated by the Imperial telegraph department.

A central depôt has also been provided for meeting the requirements in telephone and telegraph material of the cavalry, infantry, pioneers, and telegraph troops. The manager of the depôt always has in stock a quantity of the necessary materials. The reserve is

13

kept in trucks on rails, and each box is at once accessible and bears amindication of its contents. The deliveries from the depôt to the troops are effected partly direct by rail and partly by means of heavy motor lorries, which frequently have to be driven almost to the trenches, whilst special depôts are provided for furnishing telephone materials to the artillery.

Buffer Batteries for Alternating-Current Systems.—An illustrated account of experience with buffer batteries on alternating-current systems is given by L. Schroeder in the E.T.Z., the fundamental idea being shown in fig. 1. G is the three-phase generator which supplies energy to the three-phase bus-bars BC, while N is the network; MD is a motor generator. The latter acts in co-operation with the storage battery A. In the bus-bars a feries transformer is provided, the secondary current of which is febtified by means of the synchronous converter B. The direct current which comes from the synchronous converter is approximately proportional to the current in the network, and is used to regulate the booster Z. For this purpose the direct-current from R is passed through the magnetising winding ab of the booster This booster has also a second excitation winding ab and cd act in opposition, and are so dimensioned that at the average load in the network the actions of the two windings counterbalance each other, so that the booster is unexcited and the battery is

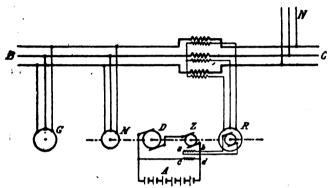

FIG. 1.-WIRING ARRANGEMENT FOR BUFFER BATTERY.

neither charged nor discharged. If the load in the network increases, the action of the winding  $a\,b$  is greater than that of  $c\,d$ , and the booster is now excited in such a way that the storage battery is being discharged. The battery, therefore, drives the direct-current generator  $\mathbf{n}$ , and the three-phase alternator  $\mathbf{m}$  now becomes a generator and supplies energy to the network. On the other hand, if the load in the network decreases below the average value, the storage battery  $\mathbf{A}$  is charged. For the regulating generator  $\mathbf{n}$  use is not made of an ordinary synchronous converter, but of a Dantelson converter, with the modification due to Woodbridge. This arrangement was used in tests in which the normal load of

FIG. 2.—RESULTS OF TESTS.

the network was 35 kW. The battery consisted of 106 cells, with a discharge current of 259 amperes for one hour. The results of the tests are given in fig. 2, in which Curve 1 represents the load of the network in kilowatts, Curve 2 represents the load of the dynamo in kilowatts, while Curve 3 represents the voltage in the network. The abscises represent minutes. It will be seen that even though the load in the network was increased to 108 kW.—that is, more than three times the normal load—the buffer battery arrangement acted quite satisfactorily. If the generator suddenly stops work and the battery is forced to supply the whole current, the voltage in the network drops, but can be brought up to its normal value quickly by a simple change of connections.—Electrical World.

Shortage of Switchboard Attendants.—Our contemporary, Electrical Engineering, has prepared a scheme for enrolling in Electrical Emergency Service as volunteer switchboard attendants for part time, electrical men who are ineligible for active service and are willing to assist in cases of emergency. Particulars may be obtained on application to our contemporary at 203, Temple Chambers, London, E.C.

Parliamentary.—Dewsbury Corporation, after being before Mr. W. Middlebrook's Select Committee of the House of Commons on various dates during the past month, was ordered on Friday to be reported to the House for third reading. Mr. Vesey Knox, who represented the Corporation, explained that an agreement had been arrived at with regard to the tramways portion of the Bill. The Corporation were asking for powers to construct additional tramways and for further powers over the existing tramway and electricity undertakings. The Corporation desired to link up the whole system in the borough and secure running powers over the whole of the lines either of themselves or of those with whom they might make them lessess or licensees when the present agreements came to an end in 1933.—Mr. Councillor J. E. Kilburn (chairman of the Tramways Committee) stated that the Corporation were satisfied with the agreement which had been made by the parties concerned.

SHEFFIELD AND ROTHERHAM TRAMWAYS.—The Select Committee of the House of Lords, presided over by the Duke of Wellington, considered the Bills promoted by the Sheffield and Rotherham Corporations together. Mr. Vesey Knox, K.C., and Mr. Gee appeared for the Rotherham Corporation, and Mr. H. Lloyd, K.C., and Mr. Tyldesley Jones for the Sheffield Corporation. The Rotherham Bill dealt with various matters, and included powers for doubling a portion of the existing track, the laying of a single track in the direction of Maltby, and for making arrangement for through running between Sheffield and Rotherham. The Sheffield Bill contained powers for the construction of new tramways, and for the purchase of the tramway in that part of Tinsley now taken into the city, which belongs to the Rotherham Corporation. Mr. Vesey Knox explained that the only opposed part of the Bill of the Rotherham Corporation was with regard to what was to become of the Tinsley tramway. The Sheffield Corporation proposed in their Bill to purchase this tramway, which was the property of Rotherham until 1926. The two places were competing in tramways, and the Tinsley line was the link between the two larger systems. There had been through running up to September, but in consequence of differences of opinion about halfpenny fares, the through service had been suspended. The Sheffield Corporation threatened to run motor-omnibuses to compete on the route, and the Rotherham Corporation promoted the Bill to prevent this being done. This was followed by the Sheffield Corporation promoting their Bill to compulsorily acquire the Tinsley tramways. After several unsuccessful consultations between the parties to arrive at an agreement, the Committee passed Olause 14 of the Rotherham Bill, which 'provided for through running, with the addition that nothing in the Act should interfere with the running of motor-buses by the Sheffield Corporation until such time as the Board of Trade should be able to decide the question. The parties subsequently came to terma as t

"Sole Agents."—" One of Several Sole Agents" writes as follows:—"Some time ago a very plausible person called on us, with what he described as telephone shields for attaching to telephone transmitters to prevent contagion. He laid great stress on the fact that they had been passed by H.M. Postmaster-General on a date stated, and also that if we purchased a small stock we were to have the sole agency, &c. It was a cash transaction, and goods were left, but we afterwards discovered at least three sole agents existed in one small town, and efforts to get in touch with his firm resulted in numerous addresses being reported 'Gone away, no address.' We strongly advise electrical clients and stores to think twice before taking up the 'Sole agency' until they have tried the goods. A 'Sale or return' arrangement would be much better."

A Business Club for London.—Owing to the lack in London of a Commercial Club of national or imperial scope, steps are being taken to meet the want, which is described as a great inconvenience to the manufacturers, merchants, shippers and business men of the British Isles, and is, above all, keenly felt by commercial visitors from our Colonies and foreign buyers visiting the metropolis for business purposes. The Council of the British Empire Industrial League have given serious consideration to this matter, and are making arrangements to found in London the British Empire Commercial Club on such a basis as will supply what cannot be otherwise regarded than as a metropolitan, national and imperial requirement. It is hoped that the Club will receive the hearty and generous support of our manufacturers, exporters and wholesale and retail merchants, and other leading men connected with business.

War Office Contracts and Workers' Badges,—In the House of Commons, on Tuesday, Mr. Baker stated that arrangements were complete for the issue of badges to workmen engaged on War Office contracts, but it had been decided to limit them to skilled workmen engaged in the manufacture of munitions of war. Mr. Terrell asked if "munitions of war" included electrical equipment in the field, and Mr. Baker replied that he thought the answer would be in the negative.

Fatality.—John Sterling, who was employed at the coal-outting machine at Derryloanhead Pit, Derry, was found dead in the mine on Monday morning, having apparently been killed through coming in contact with an electric cable

Electrical Prosperity Week.—The Society for Elec-Electrical Prosperity Week.—The Society for Electrical Development, U.S.A., has, as already stated, decided to hold an "Electrical Prosperity Week" during the first week in December next, and has appointed a strong Committee to conduct the preparatory campaign, Mr. H. W. Alexander having charge of the publicity work, and Mr. J. M. Wakeman being the general manager. Local agents have been appointed to handle the campaign in 50 centres, and every known device will be employed to ensure its success. It is stated that "this big movement will unquestionably be the greatest educational and sales campaign ever carried on in the history of the industry." the history of the industry

the history of the industry."

The scale upon which the Society is preparing for its great campaign is evidenced by the fact that £10,000 has been allocated to special expenditure for advertising purposes, in addition to a still larger outlay on other items. The money will be provided out of the regular subscriptions of the Society's members. Leading electrical manufacturers and dealers have also declared their intention of spending large sums on national publicity. The week will date from November 29th to December 4th, 1915. Advisory Committees have been appointed on general publicity, advertising, exhibitions and lectures, and on local displays, and local Committees will also be formed. It is anticipated that fully £100,000 will be spent on this, "the greatest campaign in trade history," before its close.

Copper.—Mid-monthly returns, as tabulated in Messrs. H R. Merton's statistical circular, show an increase in European visible supplies of 315 tons. English supplies, since March 31st, show a decrease of 210 tons. From the figures relating to detailed supplies, it appears that European arrivals from North detailed supplies, it appears that European arrivals from North America appear to be slightly lower than for last month, though very considerably higher than the quantity for November, 1914, or February, 1915, in fact they promise to exceed the supplies for any month of the last eight, except March. Supplies from Spain and Portugal to Eugland and France for the fortnight are at a rate of double the pre-war average, but it is probable that this rate will not be kept up, shipments from these countries always varying considerably from month to month. Chile shipments are considerably above pre-war average: Australian however are below. siderably above pre-war average; Australian, however, are below. Total deliveries are not at such a high rate as last month but at a higher rate than any other month since July.

Appointment Vacant.—Switchboard attendant (30s.) for Psymouth electricity works. Particulars are given in our advertisement pages.

The Coal Supply.—Last month a deputation representing the industries which are large consumers of coal waited upon the Board of Trade, and drew attention to the abnormally high price of coal, with a view to obtaining the intervention of the Government, and, if possible, the fixing of fair prices. Up to the present but little benefit has been derived from this action, though a Committee appointed by the Board of Trade has published. lished a report which bears out the statements made by the deputation. At a meeting of the Manchester District Institution of Gas Engineers on Tuesday last week, reported in the Journal of Gas Lighting, the question was discussed, and it was agreed that influence ought to be brought to bear upon members of Parliament with a view to urging the Government to take immediate action in the direction of restricting the export of coal, facilitating transport by rail, and preventing unnecessary increases in the price of coal for next year's requirements.

The meeting also recommended that a conference of gas and electrical undertakings throughout the country should be called as

soon as possible,

Commenting on this subject, our contemporary laments the inaction of the Board of Trade, and regards the outlook as very serious, particularly in view of the apparent inability of the authoof the miners for a 20 per cent. war bonus increases the gravity of the situation, and the Journal rightly condemns the self-seeking tendency which is so manifest, at a time when every man should put his shoulder to the wheel. The attitude of the coal-owners is especially reprobated, as it is stated that they are endeavouring to make appointment profits beyond all vessels.

to make exorbitant profits, beyond all reason.

The Journal supports the proposal that the gas and electricity industries should join forces, and suggests that the central organisations of the two industries should take immediate action

towards this end.

We cordially welcome the suggestion, and trust that it may be quickly carried into effect. Recent articles in our columns have indicated the difficulties that are being met with by electricity works, and unless strong action is taken there is every likelihood that these difficulties will become more acute, very much to the detriment of the industry.

It rests with the Council of the Institution of Electrical Engineers to take the first step towards holding a National Conference, and station managers who desire relief from the present burden, and safeguards against additional burdens, ought to lose no time in pressing their views upon that body by letter and by personal representations to its members.

Electric Vehicle Committee.—The question of increasing the sales of the Journal was considered at the meeting held on April 15th, the Committee feeling that electricity supply undertakings might do much more in the way of utilising the

Nournal for distribution among prospective users in their distribution. It was, reported that many undertakings were restricting their expenditure on publicity material during the war, owing to the regulation of the Government prohibiting further capital expendi-

ture on ordinary mains extensions, and also limiting expenditure generally. It was resolved to point out to the undertakings that the adoption of electric vehicles did not necessarily entail seven extension of the mains or plant. The supply was entirely an "off-peak" load, and undertakings on that account should, at the present time, use every endeavour to make known the advantages of electric vehicles. Undertakings are to be asked to make use of the publicity mail cards prepared by the Committee, the demand for which has been very small indeed, and confined to a very few undertakings up to the present.

Those undertakings in the Metropolitan area that charge more than 1d. per unit for electric supply to vehicles have been asked to come into line with the Committee's recommended tariff of 1d. per unit, but no satisfactory reply has been received from any underture on ordinary mains extensions, and also limiting expenditure

unit, but no satisfactory reply has been received from any under-taking to which the letter has been addressed.

It was reported that certain undertakings had found it necessary to advance prices all round owing to the increased cost of coal, &c.

It was decided that where such advance in price was only of a temporary nature, the undertaking concerned should still have its name in the list in which it at present stands on the tariff sheet of the

As there are vehicles not fitted with the standard recept As there are vehicles not fitted with the standard receptacle which come to certain stations for charging, the Committee decided to insert a paragraph in the next issue of the Journal, advising electric supply undertakings to do what they can to persuade the owners of such cars to have the standard receptacle fitted.

The secretary was also instructed to get into touch with the American manufacturers of electric vehicles, pointing out the necessity of fitting the standard receptacle.

Another meeting had taken place between representatives of the Tungsten Lamp Association and the E.V.C. Technical Sub-Com-

Tungsten Lamp Association and the E.V.O. Technical Sub-Committee regarding the standardisation of metal-filament lamps for use on electric vehicles. It was decided to adhere to the recommendation that the lamps used should be for a pressure of 12 volts, and in accordance with the requirements of the British Engineering Standards Specification No. 69.

Further progress has been made with the preparation of the report upon battery charging equipments and methods of charging, and it is hoped shortly to have it ready for issue.

The next meeting of the Committee has been fixed for May 11th.

### OUR PERSONAL COLUMN.

The Editors invite electrical engineers, whether connected with the technical or the commercial side of the profession and industry, also electric tramway and railway officials, to keep readers of the ELECTRICAL REVIEW posted as to their movements.

Central Station Officials.—An interesting presentation took place at Beackpool electricity works on April 15th, when a token of friendship in the shape of a kit bag was given to Mr. E. HARDMAN, who is leaving the staff to take up a position with a Yorkshire electrical car company. Mr. Parkinson made the

MB. J. H. SPARROW, Southsea, has been appointed switchboard attendant at the Bermondsey electricity works. There were six

applications for the post.

MR. FRANCIS D. LARCOMBE has resigned his position as control engineer for the Yorkshire Electric Power Co. after ten years' engineer for the forkshire Electric Fower Co. after ten years
service to take up a position on the commercial organisation of the
British Westinghouse Co., Manchester.

Mr. Fowles, of Erith, has been appointed chief assistant electrical engineer to Aylesbury U.D.C. There were 42 applicants,

Mr. H. M. Theaker, shift engineer of Manors Power Station,
Newcastle on-Tyne Corporation Tramways, was married to Miss.

Mand Robinson, of Mossley, nr. Manchester, at Scouthead, Oldham, on April 14th.

Tramway Officials. — The Southampton Tramways Committee has unanimously resolved to appoint Mr. W. T. ROBSON, A.M.I.E.E., of South Shields, as tramways manager, at a

salary of £400 per annum.

MR. J. J. McMahon, electrical engineer in the overhead department of the Manchester Corporation tramways, who, as reported in our columns recently, was a passenger on the Aguila, which was torpedoed by a German submarine, reached Manchester safely last week, and was welcomed back by a small party of Councillors and tramway officials. Mr. McMahon was picked up by the sall plumouth, bound for Madeira, and, when the vessel reached that port, he felt so shaken by his experience, that he decided to return

General.—MR. G. JACKSON, of the technical staff of the British Insulated and Helsby Cables, Ltd., Helsby, has been presented by his colleagues with a handsome set of carvers upon the occasion of his marriage. The presentation was made by Mr. A. E. Bayles, chief of the technical staff.

MR. JOHN F. SKINNER, Mitchelstown, has been appointed elec-

MR. JOHN F. SKINNER, Mitchelstown, has been appointed electricisn at the Clonmel Lunatic Asylum,

MR. M. BARRINGTON BAKER, A.M.I.E.E., has completed his contract for the Crown Agents in Zansibar, and is now proceeding to Hong Kong as chief assistant engineer to the China Light and Power Co., Ltd.

Obituary.—E. J. Ljungberg.—We regret to read in the Ironmonger of the death which occurred on April 5th, in Stockholm, of Mr. E. J. Ljungberg, managing director of Stora Kopparberg Co., of Falun, aged 73. The company with which the deceased was connected was one of the oldest and largest trading Corporations in Scandinavia. "Mr. Ljungberg thoroughly mastered the working of the various departments, both from the technical and the commercial point of view, and was responsible for many schemes and improvements for increasing the productive for many schemes and improvements for increasing the productive capacity of the company's extensive properties. He it was who first installed the plant for the manufacture of pig-iron by electricity. He was one of the ablest men his country has ever produced, and has justly been described as the 'grand old man' of Swedish industry and trade."

MR. I. A. MOSERIAN — The death occurred on April 14th, at

MR. J. A. MACLELLAN.—The death occurred on April 14th, at Newton Abbot, of Mr. John Alexander MaoLellan (of Mesers. Alley & MacLellan, Ltd., of Glasgow), at the age of 61 years. The Times reports the death, at the age of 83 years, of MR. H. M.

MATTHEWS, M.C.E., who was selected to examine and report on the lighthouses of the coast in 1878.

the lighthouses of the coast in 1878.

The death has taken place, at the age of 63 years, of Mr. Wm. Franklin, who had for many years been connected with the electrical department of Messra. W. T. Hunley's Co., Ltd., at Woolwich.

By a printer's error in our last issue, we stated that the late Mr. David Smith became secretary of the United River Plate Telephone Co. in November, 1914. This should, of course, have read 1904.

#### NEW COMPANIES REGISTERED.

Cromble's Patents, Ltd. (139,979).—This company was registered on April 16th, with a capital of £4,000 in £1 shares (2,000 10 per cent. non-cum. participating preferred), to acquire and turn to account a certain invention relating to improvements in apparatus and processes for the purification of liquids and the recovery of solids contained therein, to carry on the business of electricians, electrical engineers, suppliers of electric apparatus, etc., and to adopt an agreement with L. H. Raw. The subscribers (with one preference share each) are: W. C. Smith, "Montague," Durley Road, Bournemouth West, gentleman; L. H. Raw, Blomfield House, London Wall, E.C., engineer. Private company. The number of directors is not to be less than two or more than five; the subscribers are to appoint the first. Solicitors: Francis & Johnson, 19, Great Winchester Street, E.C.

H. L. V. Pearn and Co., Ltd. (139,951).—This company was registered on April 14th, with a capital of £1,000 in £1 shares, to acquire from A. E. Lamkin, of 86, Springfield Road, Brighton, electrical engineer, the benefit of certain inventions, to develop and turn to account the same, to carry on the business of electricians, mechanical engineers, suppliers of electricity, etc., and to adopt an agreement with the said A. E. Lamkin, 86, Springfield Road, Brighton, electrical engineers, auppliers of electricity, etc., and to adopt an agreement with the said A. E. Lamkin, F. H. Hadow, and H. L. V. Pearn. The subscribers (with one share each) are: A. E. Lamkin, 86, Springfield Road, Brighton, electrical engineer; H. L. V. Pearn, 134, Queen's Park Road, Brighton, gentleman; F. H. Hadow, 15, Harrington Gardens, S.W., gentleman. Private company. The number of directors is not to be less than two or more than five; the first are A. E. Lamkin, H. L. V. Pearn, and F. H. Hadow (chairman), Qualification, £100. Secretary, G. O. Gilland. Registered office: 3-7, Southampton Street, Strand, W.C.

W.C.

Pearson's Electric Miners' Lamp Co., Ltd. (139,974).—
This company was registered on April 15th, with a capital of £5,250 in 5,000 participating pref. shares of £1,000 each and 5,000 "B" shares of 1s. each, to carry on the business of manufacturers of and dealers in electric miners' safety lamps, accumulators, butteries, switchboards, charging boards and stands, electric light bulbs and fittings, lamps, radiators, condensers, and all other electrical appliances, etc. The subscribers (with one participating pref. share each) are: G. J. B. Porter, 2, Wardrobe Place, Doctors' Commons, E.C., solicitor; H. A. P.—(?), 7, St. Kilda's Road, Stoke Newington, N., secretary; W. H. J. Welch, Namona, 349, Wanstead Park Road, Illord, factory manager; J. Baker, 77, Lyndhurst Avenue, Streatham Hill, S.W., clerk; W. J. White, 2, Melrose Avenue, Mitcham, traveller; E. Mills, 48, Arodene Road, Brixton Hill, clerk; F. W. Godwin, 34, Madeira Road, Streatham, S.W., clerk. The first directors (to number not less than two or more than seven) are G. J. B. Porter, E. F. Hilton, B. R. Reale, G. Pearson, and L. R. Pearson. Qualification, 100 shares. Solicitors: Farrar, Porter and Co., 2, Wardrobe Place, Doctors' Commons, E.C.

#### OFFICIAL RETURNS OF ELECTRICAL COMPANIES.

Electric Reduction Co., Ltd.—Particulars of £25,000 debentures, created February 9th, 1915, filed pursuant to Section 93 (3) of the Companies (Consolidation) Act, 1908, the whole amount being now issued, charged on the company's undertaking and property, present and future, including uncalled capital. No trustees.

Midget Lamp Co., Ltd.—Particulars of £800 debentures, created April 8th, 1915, filed pursuant to Section 93 (3) 6, the Companies (Consolidation) Act, 1908, the amount of the present issue being £600. Property charged, the company's property, present and future, including uncalled capital. No trustees A memorandum of satisfaction in full on April 8th, 1915. of debenture dated December 30th, 1911, securing £100, has also been partified.

#### CITY NOTES.

#### Evered & Co., Ltd.

directors report, after providing for debenture interest The directors report, after providing for debenture interest £1,390; and income tax £555, a net profit of £7,639, plus £2,116 brought forward. They recommend a dividend of 4 per cent. free of income tax (£6,830), writing off plant £1,000, and carrying forward £1,925. The death is recorded of Mr. J. D. Davenport, who had been a director since 1886. The directors regard the result of the year's trading as on the whole not unsatisfactory, bearing in mind the exceptional conditions that obtained after the outbreak of war. Up to the end of July, the course of business had been much upon the lines anticipated in the last report; and while uncertainty as to the duration and effect of the war renders it impossible to form any trustworthy estimate for the present year, shareholders will be interested to know that the company has in hand large contracts for war material, that will be a set-off against the direct and indirect losses to be expected in the company's normal trade. The company's debentures fell due for payment on April 1st, 1915, and, although not affecting the figures for the year under review, it may not be out of place to mention here that the sum of £20,600 has been renewed for five years by agreement, and the balance, £9,350, paid off. The directors have elected Mr. Edward T. Read to a seat on the board. Plant and premises have been maintained in good and efficient condition, and stocks taken at or below cost. Annual meeting: April 28th.

## Johnson & Phillips, Ltd.

The profit on trading accounts, etc., for 1914, after providing for bad and doubtful debts, and after charging to revenue more than £7,000 for maintenance of buildings, plant, etc., is £37,119, plus £12,755 brought forward. There fall to be deducted: Directors' and other remuneration, £1,862; interest on debenture stock, £6,085; debenture sinking fund reserve, £6,823; interest on second debentures, £2,500; depreciation on machinery and plant, etc., £8,158; interest on loan, £150. A dividend of 5 per cent. on the ordinary shares will absorb £8,750, leaving £15,546 to be carried forward. Annual meeting: April 29th.

Babcock & Wilcox, Ltd.

The directors report that the net profit during the year amounts to £402,947, plus £73,835 brought forward, making £476,782. After deducting the interim dividends of 3 per cent. on the preference shares, 2½ per cent. on the second preference shares, and of 5 per cent. on the ordinary shares, amounting to £90,431, there is a balance of £386,351, from which the directors recommend that the following dividends be paid for the half-year ending December 31st, 1914, viz.:—3 per cent. on the preference shares £3,000, 2½ per cent. on the second preference shares (from both of which income tax is to be deducted) £4,459, 9 per cent. on the ordinary shares (free of income tax) £149,400, placing to the reserve fund £150,000, granting to the staff pension fund £10,000, and leaving a balance to be carried forward of £69,492. The business followed its usual course in 1914 until the war broke out. After this, the volume of new orders for stationary boilers decreased. The company has been able to manufacture some war material, required by the Government, at its Renfrew works, and having suitable buildings available at its tube works at Dumbarton, has equipped these with tools and appliances for mechaning shalls which are forgred, at the Penfson. THE directors report that the net profit during the year works, and having suitable buildings available at its tube works at Dumbarton, has equipped these with tools and appliances for machining shells, which are forged at the Renfrew works. Regular operation of this equipment has now commenced. The works at Renfrew have been well maintained, and plant and machinery have been added there to provide increased output of Government orders. The activity of the works and administrative organisations is unremittingly and preferentially devoted to Government requirements. About 800 of the staff and workmen have joined the Forces, and the board contributed to the maintenance of their dependents, and to the various war charities, upwards of £7,000 to the end of 1914. In common with other engineering firms, the company's output has been interrupted by strikes and other labour restrictions, and it has been hampered likewise by the scarcity of skilled men owing to so many joining the Forces. scarcity of skilled men owing to so many joining the Forces. Apart from affecting the cost of Government work, these labour troubles affect the cost of the company's other contracts, particularly those entered into some time before the outbreak of war, which are now in course of being carried through.

#### Annual meeting: April 28th.

#### Anglo-Portuguese Telephone Co., Ltd.

The directors' report for the year ended December 31st, 1914, states that the assets and liabilities in Portugal have been made up at the exchange ruling on that date. Provision has, states that the assets and liabilities in Portugal have been made up at the exchange ruling on that date. Provision has, as usual, been made to safeguard the company from any serious consequences arising from fluctuations in exchange during the current year. The profit and loss account shows a gross revenue of £71,339, of which operating, management and general expenses absorbed £42,651, and royalties to the Portuguese Government £2,024, leaving a gross profit of £26,664. After providing for debenture interest £2,046 and sinking fund £1,554, the amount available for disposal, including £6,870 brought forward, is £29,934. Of this it is proposed ing £6,870 brought forward, is £29,934. Of this it is proposed to place £2,500 to exchange fluctuation account and to apply £10,000 to the formation of a renewals fund. In October last the directors paid an interim dividend of 3 per cent. less income tax amounting to £4,462. They now recommend the shareholders to declare a further dividend of 5 per cent., less tax, making a total distribution of 8 per cent. for the year 1914. This will absorb £7,500 and leave a balance of £5,472 to be carried forward. The directors have desided to appropriate \$20,000 of the reserve fund to the reduction of the capital expanditure account. Further depreciation is adequately covered by the unappropriated reserve fund and the renewals fund. The managing director, Mr. F. W. Kerr, visited Lisbon in January for the purpose of inaugurating of which was attended by Exchange, the successful opening of which was attended by representatives of the Government and local authorities and the British Minister. Mr. Gill, the company's consulting engineer, on a recent visit to Lisbon, reported that he was pleased with the condition of the North, Central, and Trunk Exchanges at Lisbon.

Annual meeting: April 23rd.

### Oriental Telephone & Electric Co., Ltd.

Oriental Telephone & Electric Co., Ltd.

The directors report that for the year ended December 31st last, including £43,221 brought forward, and after deducting the interim dividends paid on the preference and ordinary sbares, and making the necessary provision for redemption of the debenture stock and other charges as shown in the net revenue account, the amount to be dealt with is £78,128. The directors recommend a final dividend of 3 per cent. (less income tax) for the year on the preference shares, absorbing £1,500, a final dividend of 6 per cent. (free of income tax) on the ordinary shares issued, making 10 per cent. for the year, requiring £10,759, transferring to reserve account £5,000, to staff pension fund £2,009, and carrying forward £58,869. The revenues and the number of new subscribers at the various exchanges belonging to this company have increased during the year in every instance, as is the case with the subsidiary companies. The Bombay Telephone Co., Ltd., has further increased its dividend to 16 per cent., whilst the Telephone Company of Egypt, Ltd., the Bengal Telephone Co., Ltd., and the China and Japan Telephone and Electric Co., Ltd., have paid the same dividend as last year, viz., 10 per cent., 7 per cent., and 5 per cent. respectively. To meet the cost of further large extensions and improvements, the Bengal Telephone Co. during the year has increased its capital by an additional Rs. 1,000,000 in Rs. 100 shares, of which one half were issued. This company subscribed and paid for 2,209 of these shares at par, thus raising its holding in the Bengal Co. to 7,750 shares. The new exchange premises of the company at Port Louis, Mauritius, were opened in May last. New subscribers continue to join, and a small sub-exchange has been opened at Moka. It will shortly become necessary to lay an undergrouhd cable from Port Louis to Curepipe in order to provide a thoroughly efficient trunk telephone service between these two places and other up-country exchanges.

Annual meeting: April 28th. THE directors report that for the year ended December 31st

#### Potteries Electric Traction Co., Ltd.

THE capital expenditure during 1914 amounted to £12,072. The revenue amounted to £129,855. The traffic receipts, which amounted to £115,083, show an increase of £5,158. After deducting all expenses chargeable to revenue, including £11,303 for debenture and other interest, there remains £35,825, as compared with £38,529 for 1913. Adding £749 brought forward, there is a balance available for distribution of £36,574. There is to be placed to reserve account £6,500. brought forward, there is a balance available for distribution of £36,574. There is to be placed to reserve account £6,500, and to renewals account £10,000. A dividend at the rate of 5 per cent. per annum on the preference shares absorbs £12,250, a dividend at the rate of 2½ per cent. per annum on the ordinary shares will absorb £6,125, and there is to be carried forward £1,699. The reserve account will then stand at £29,500, and there will be a credit balance on the renewals account of £26,520.

Negotiations were commenced during the year and are proceeding with the Stoke-on-Trent Corporation, with the object of securing the postponement by the Corporation of their right to purchase certain portions of the company's undertaking in the years 1917 and 1918. The omnibus service commenced in 1915 was extended during the year to other outlying towns and villages. The receipts from the omnibuses are included under the heading of traffic receipts in the revenue account. Since the close of the period covered by this report the War Office have impressed six of the company's omnibuses, and owing to the difficulty in replacing them at the present time the services have had to be curtailed. On the outbreak of war Mr. G. F. M. Cornwallis West, the late chairman, was recalled to the Colours, and has since retired from the Board, Mr. R. J. Howley, one of the managers of the B.E.T. Co., Ltd., was elected a director and appointed chairman. Messrs Stephen Mear and F. W. Chanter are the directors retiring by rotation, and offer themselves for re-election.

### Clevedon, Portishead and District Electric Supply Co., Ltd.

THE annual meeting was held on the 14th inst., Mr. THOMAS RICHARDS presiding. The Chairman said that they were looking forward to an increase of business in the ensuing year. The directors had recently made a contract with the Bristol

Corporation for the supply of electricity in balk, and an arrangement had already been made with the South Liberty Colliery Co., at Long Ashton, to supply them with electrical power upon mutually advantageous terms. The residents of Long Ashton being desirous of having an electric lighting supply for their village, the company hoped to arrange for this extension, as the colliery was in the immediate vicinity. It was also proposed to extend the mains for the delivery of curextension, as the colliery was in the immediate vicinity. It was also proposed to extend the mains for the delivery of current from this source to Portishead, with the hope of being able to arrange with the Docks Committee for the supply of electricity for power and lighting at the Portishead Docks, negotiations for which were in progress. In any case, it was desirable that the cable should be extended to Portishead from Long Ashton, because this would afford facilities for the supply of electric light to the residential suburb of Leigh Woods, and the villages of Abbot's Leigh, Pill, and Portbury, adjacent to which the cable would be laid. These contemplated extensions would require additional capital, and after consideration the directors thought that rather than issue debentures at present, as intimated in the report, it would be better to offer preference shares of £1 each, bearing interest at 6 per cent. per annum. Financial arrangements had already been made to the extent of £9,000, and it was hoped shareholders and their friends would subscribe the remaining £3,000 to make up the total of £12,000, the approximate cost of the proposed extension, the sanction of the Treasury having been received for the issue of additional capital to this extent.

Mr. Napier said in comparing the revenue of the present quarter with that of the corresponding quarter of last year, it would be seen that there was a 20 per cent. increase.

Mr. Frank Christy reviewed the progress of the company, and referred to the negotiations for the contemplated extension. With regard to the South Liberty Colliery, he felt they had made an agreement which was equitable to both sides, and they were daily expecting the confirmation of the necessary Order from the Board of Trade for the work to be begun. It was anticipated that if no delays occurred this service would be installed early in the autumn.

be installed early in the autumn.

#### Windsor Electrical Installation Co., Ltd.

SIR W. SHIPLEY presided recently at the annual meeting. After referring to the death of Mr. Riley, who had been a director for nearly twenty years, he said that the war had, of course, adversely affected the financial position of the company, both in regard to receipts and working expenses. In Windsor they had suffered more severely than many towns Windsor they had suffered more severely than many towns owing to the Government lighting restrictions and the earlier closing of licensed houses, and by the Court not taking up its residence there as usual. Up to the war they had about 3,000 additional 8-c.p. lamps either connected or waiting—which was a record for recent years—and the total connections for the remainder of the year were about 900 lamps. Their revenue did not show an appreciable decline; while there had been a large increase in cheap power units sold, the revenue from the more profitable units had considerably declined. Receipts from the sale of current showed a good increase for the first half-year, but that was more than wipsel out by decreases in the latter half, notwithstanding the benefit derived from the occupation of houses by the military authorities. The higher working costs were largely due to increased cost of fuel. Wages were higher, as nearly the whole of the station staff had joined some branch of the military service, and their places had been filled by others at wages ruling considerably higher than at the outbreak of war. They might have to consider the advisability of slightly increased the contract of the contract of the places had been filled by others. at wages ruling considerably higher than at the outbreak of war. They might have to consider the advisability of slightly increasing the price of current. In recommending a reduced dividend they had done what many companies had been compelled to do, but taking all the facts into consideration the result might be regarded as satisfactory. Their financial position was quite sound, and the increased business that they were now getting would show in the accounts directly the Government lighting restriction was removed, so that they had cause to be hopeful that the improvement in the results would be resumed.

Mr. H. L. Prior seconded, and the report was adopted.

### Musselburgh and District Electric Light and Traction Co., Ltd.

THE profit for the year 1914 was £7,547, and after deducting therefrom debenture interest, amount set aside for redemption of debentures, allowance to dependents of employés on active service, and depreciation on furniture, fittings, plant and tools, there remains a balance of £2,447, plus £257 brought forward. There is to be put to reserve and renewals account—tramways £2,000, and lighting £500, leaving £204 to carry

forward.

Tramways £2,000, and ngming 2000, 1000 forward.

Tramways Undertaking.—There is an increase of £673 in the profit as compared with 1913, but the traffic receipts since the declaration of war were seriously affected, particularly during the holiday season. The motor omnibuses purchased in 1905, the value of which stood at £2,003, have been scrapped, and the cost charged to tramways reserve and renewals accoust,

int the amount which the directors recommend should be transferred to this account practically counterbalances the amount taken out.

Lighting Undertaking.—There is a decrease of £180 in the profit as compared with 1913. The receipts showed an increase of £235, but there was an increase in the expenditure of £425, principally under the heading of repairs and maintenance. The directors, however, are satisfied that this expenditure he been justified by the state of the plant generally at the present time, and they are advised that there should be a decrease under this heading during the current year. During 1914, Dr. Loewenfeld resigned his seat on the board, and the vacancy was filled by the appointment of Mr. R. Watson, who for some time past has been the commercial manager of the company at Musselburgh, and formerly secretary of the company.

The annual meeting was held on April 15th at 3, Laurence Pountney Hill, E.C., Mr. L. B. Schlesinger in the chair. The Chairman said that the tramway portion of the undertaking continued to show progress, but had it not been for the war that progress would have been much more marked. The traffic receipts from January 1st to the beginning of August showed an increase of nearly £700 over those for the corresponding period of 1913, but from the date war was declared there was a decrease in the receipts, and at the end of the year the actual increase had fallen to £250. Owing to the war the daily average receipts showed a decrease. Had times been normal there was every reason to believe that the increase war the daily average receipts showed a decrease. Had times been normal there was every reason to believe that the increase of £700 at the beginning of August would have been increased to certainly over £1,000 by the close of the year. The receipts this year up to date showed a decrease of £700 compared with the corresponding period of 1914. That decrease was due not only to the effects of the war, but also to a strike of the compared with the corresponding period of the compared with the corresponding period of the compared with the compared with the compared with the compared with the compared with the compared with the compared with the compared with the compared with the compared with the compared with the compared with the compared with the compared with the compared with the compared with the compared with the compared with the compared with the compared with the compared with the compared with the compared with the compared with the compared with the compared with the compared with the compared with the compared with the compared with the compared with the compared with the compared with the compared with the compared with the compared with the compared with the compared with the compared with the compared with the compared with the compared with the compared with the compared with the compared with the compared with the compared with the compared with the compared with the compared with the compared with the compared with the compared with the compared with the compared with the compared with the compared with the compared with the compared with the compared with the compared with the compared with the compared with the compared with the compared with the compared with the compared with the compared with the compared with the compared with the compared with the compared with the compared with the compared with the compared with the compared with the compared with the compared with the compared with the compared with the compared with the compared with the compared with the compared with the compared wit pany's employés, which, he was glad to say, was now ended. With regard to the electric lighting undertaking, it was satisfactory to note the increased revenue. Part of that increase factory to note the increased revenue. Part of that increase was due to a temporary supply to some stores in Musselburgh owing to the breakdown of their plant. The supply was, however, still being given, and was likely to be taken for some weeks yet. There had also been a satisfactory increase in consumers for both lighting and power. Notwithstanding the increased revenue there was a decrease in the net profit of £180, due principally to expenditure on repairs and maintenance subsequent to the appointment of the new engineer. The board were advised that there should be a decrease under this heading during the current year unless something unforeseen happened. If the lighting undertaking did as well during the current year he thought they would have reason to be satisfied, owing to the increased price which they were now having to pay for coal, oil, and materials of every description. satisfied, owing to the increased price which they were now having to pay for coal, oil, and materials of every description. They had a contract with the Musselburgh Town Council for street lighting, but the lighting had been considerably reduced in accordance with instructions received from the military authorities, and the question of a rebate to be allowed to the Council in regard to the reduced consumption was now being discounted. Preceeding to deal with the precent, the Chair. Gouncil in regard to the reduced consumption was now being discussed. Proceeding to deal with the accounts, the Chairman pointed out that in the balance sheet the cost of the omnibuses which were purchased in 1905 had been written off the reserve and renewals account. Those 'buses, he said, when originally purchased were not of the high standard of efficiency reached to-day. They were absolutely out of date and practically worthless, and it was better to get them out of the accounts. They were, however, recommending the addition of \$2,000 to the reserve and renewals account to replace that accounts. They were, nowever, recommending the addition of £2,000 to the reserve and renewals account to replace that item. The lighting reserve and renewals account had been charged with the cost of installing a new traction battery, which was giving satisfactory results and which would mean a considerable saving to the company. The debenture capital outstanding was now £87,500 against £88,200, £700 having been redeemed during the year. The directors had made allowances to dependents of the company's employés on active

service.

Mr. W. B. Cownie seconded the motion, and the report was adopted.

Richardsons. Westgarth & Co., Ltd.—The report for 1914 states that the accounts, after providing £19,045 for maintaining buildings and fixed and loose plant, show a profit of £66.170. The results are very satisfactory, considering the difficulties encountered, and the fact that no assistance has been obtained from Government work during the period. The contracts booked before the war for delivery in 1915 are on the moderate basis of profit then prevailing, and most of them have had to be suspended owing to the cessation of mercantile work in the ship-yards. This will result in accumulated interest charges, while the contracts during ultimate completion will have to bear increased working charges, as well as the war bonus of 4s, per week on wages, thus rendering the present position one of considerable uncertainty.

Direct United States Cable Co., Ltd.—The directors' report for the year ended March 31st, 1915, states that the reserve fund account shows a balance of £476,986, as compared with £451,491, an increase of £25,495. This is due to the cost of cable repairs having been exceptionally small during the past year, and while the directors are pleased to report that the cables are now in good working order, they believe, in view of past experience, it is in the best interests of the company to continue the policy of building up the reserve fund to such a figure as will provide for any contingency. Three quarterly interim dividends of 2s. each par share (less income-tax), amounting to £33,643, have been declared and paid during the year, and a final dividend of 2s. per share (less tax) is now proposed, making a total distribution of 4 per cent, for the year.

Annual meeting: April 27th.

Calcutta Tramways Co., Ltd.—The report for 1914 states that the revenue, including interest on investments and deposits, amounts to £109,035, plus £8,405 brought forward. A final dividend of 6s. 6d. per share, making 9½ per cent. for the year, is recommended, transferring to reserve for depreciation, &c., £15,000; to staff provident fund, £1,258; and carrying forward £7,566. In view of the exceptional taxation rendered necessary by the war, income-tax will in future be deducted from all dividends paid.

Potteries Electric Traction Co., Ltd.—For 1914 the revenue amounted to £129,855. The traffic receipts at £115,082 show an increase of £5,167. After deducting all expenses chargeable to revenue, including £11,303 for debenture and other interest, there remains £36,824, as compared with £38,528. The directors recommend placing to reserve account £6,500, to renewals account £10,000, a dividend at the rate of  $2\frac{1}{2}$  per cent. per annum on the ordinary shares, carrying forward £1,699.

Anglo-American Telegraph Co., Ltd. — Interim dividends for the quarter ended Maron 31st, 1915, 15s. per cent. on the ordinary stock and £1 10s. per cent. on the preferred stock, less income-tax at 2s. 1d. in the £, psyable on May 1st.

Montreal Light, Heat and Power Co., Ltd.—The directors have declared a dividend of  $2\frac{1}{2}$  per cent., being at the rate of 10 per cent. per annum, for the quarter ending April 80th.

Kaministiquia Power Co., Ltd.—The directors have declared a dividend of 11 per cent., or at the rate of 6 per cent. per annum, on the Common stock, for the quarter ending April 30th.

#### STOCKS AND SHARES.

TUESDAY EVENING.

Taken as a whole, the main feature of Stock Exchange markets during the past week has been one of steady improvement and better prices. To this it cannot be said that the news from the various fronts has contributed in any great measure. Mystery overhangs the various operations, and the man in the street chafes against the absence of information as much as he is annoyed, rather than perturbed, by the various rumours afloat.

Important relief to the financial situation has been afforded by further sensational rises in American Railroad shares. At first blush, there may seem to be no connection between these and such securities as electrical supply shares, for instance. Briefly put, however, the position is that the rises in Americans have led to large sales of the shares by English holders, who have received the money and want to invest it in domestic issues. At the same time, the exchange between the two countries is assisted by the share-purchases of the United States, which help to offset the supplies ordered in this country from Brother Jonathan in connection with the war. latter consideration, affecting, as it does, the rate of exchange, is of value to all those who have commercial transactions with the States. The recovery in the price of copper has stimulated business in copper shares; and the rubber market, after a slight set-back, has made another forward movement on a small quotable scale, but accompanied by a substantial amount of support.

Mexican matters, too, are much less gloomy than they were—at least so far as the financial aspect of them is concerned. Lay readers of the news may be inclined to wonder where the beneficial change in the situation has occurred; but, whatever its cause, the fact remains that practically all securities connected with Mexico have advanced during the past few days. Mexico Tramways bonds of both classes are 5 points higher, and the Firsts are 10 up since the suggestion was thrown out here to the speculator that this particular security offered tempting scope for his peculiar talent. Mexican Light and Power Common are firmer at 201, the preferred at 42, and the

bonds stand about 46 and 29 for Firsts and Seconds respec-

Canadian Industrials also are having their turn of better markets. Large orders for British munitions of war have been placed with some of the Canadian undertakings; and Stock Exchange expectation, at any rate, looks hopefully for a wide distribution of the orders already secured and to come. (Incidentally, it may be interpolated that the Edison & Swan Co. is said to be making a new kind of small projectile for use by the British Army.) Canadian General Electric Common shares have strengthened to 91, a gain of several points on the week, and the 7 per cent. preferred rose to 107. A little business is being done in British Columbia Electric Railway issues.

With Mexican and Canadian affairs shaping more cheerily, it is meet that the Brazilian companies should also be advancit is meet that the Brazilian companies should also be advancing in public favour. The dramatic rises which have occurred in Brazil Tractions since Easter were not repeated; but the market is a hard one, and as there were a great many selling orders at 60, the mere touching of this price enabled a good number of them to be executed, leaving the way clear for further advance when the buyers return to the attack. Maybe it is not altogether outside the scope of our province to add that the market for nitrate shares has developed more strength than it has exhibited since the war started, this in its turn producing improvements in Chilean Government and commer-

that the market for nitrate shares has developed flote strength than it has exhibited since the war started, this in its turn producing improvements in Chilean Government and commercial bonds and shares.

The Home Railway market declines to be left behind in the quiet confidence which is acting as a stimulus to securities, investment and speculative alike. Some there are who regard the Government's concession to the railways as likely to turn out of no great value, but that the investing public as a whole do not share this pessimism is shown by the way in which prices of Home Railway stocks are quietly mounting. In this advance Metropolitans have shared to the extent of a point, and Districts are ½ better; though, on the other hand, there are no changes worth mentioning in Central London or Underground Electric Railways descriptions.

The Telegraph market is good all round. Indo-Europeans went up 4 points to 55. The sellers who had been worrying the market for some little time, pressing shares with a persistence worthy of a better cause, succeeded in getting rid of them; and as soon as these orders were finished, a sharp rebound took place. The Company's repetition of its previous dividend—making £3 5s. for the year—aided the raily. Great

rebound took place. The Company's repetition of its previous dividend—making £3 5s. for the year—aided the rally. Great Northern Telegraphs are £1 higher at 30, and the company has achieved the noteworthy performance of being able to increase its dividend from 20 to 22 per cent. Anglo-American Telegraph preferred and deferred are both substantially better, destruction of the usual quarterly dividends on the first-named Telegraph preferred and deferred are both substantially better, declaration of the usual quarterly dividends on the first-named and of 15s. on the ordinary stock having brought in further buyers. Eastern Telegraph rose a point. Western shares went up 5s., and an improvement of 1s. or so in West India and Panama advanced the price of the shares to 26s. 3d. Globe preference hardened to 12½, so that the yield on these shares is now reduced below 5 per cent. It is not a little surprising that, in the midst of a European war, securities such as those afforded by the telegraph industry should be maintained at prices that yield on the pre-ordinary classes something under 5 per cent. in the case of a good many.

County of London preference again rose ½, while City preference fell ½ to 12½, and Metropolitan debenture executed one of its five-point movements, this time in a retrograde direction, the price falling to 75. The Manufacturing group is a little easier, the principal feature being weakness in Edison and Swan shares. The fully-paid are 7s. 6d. lower at 35s., and the partly-paid fell a florin to 12s. 6d. British Westinghouse preference are also a trifle down.

Babooke & Wilcox shows advanced prefere relief to the contraction of the contraction of the process of the contraction of the process of the contraction of the process of the process of the process of the process of the process of the process of the process of the process of the process of the process of the process of the process of the process of the process of the process of the process of the process of the process of the process of the process of the process of the process of the process of the process of the process of the process of the process of the process of the process of the process of the process of the process of the process of the process of the process of the process of the process of the process of the process of the process of the process of the process of the process of the process of the process of the process of the process of the proc

the partly-paid fell a florin to 12s. 6d. British Westinghouse preference are also a trifle down.

Babcock & Wilcox show reduced profits, which have led to the dividend being lowered to 14 per cent., against 16 per cent. a year ago. The price of the shares at 52s. shows comparatively little change, and the report will re-assure holders of Babcock shares that they need have no fear as to the soundness of their investment. The Vickers report is also out, and the price of the shares hardened a trifle to 37s. 3d. Armstrongs are expected to declare their dividend any day now; some expect 124 per cent. the same as a year ago; others think the

are expected to declare their dividend any day now; some expect 12½ per cent., the same as a year ago; others think the company will increase the distribution to 15 per cent.

Rubber shares have benefited from the expectation that there will be an early rise—to 2s. 6d. at least—in the price of the product; while the December reports now making their appearance show that some of the companies, at any rate, have a good chance of lowering their costs to the neighbourhood of 8d. per lb. The economist will doubtless point to the improbability of an article capable of being placed on the market at 8d. a lb. selling, under normal conditions, at anything like three and a half times that figure; so that those who look ahead have some reason for their faith that rubber will come down eventually. To the strength of the copper market reference has been made already, and most of the leading copper shares have responded to the week's advance in the price of the metal. price of the metal.

Regret and sorrow have been expressed in the Stock Exchange at the sad death of Baron Reuter. Many House firms used to subscribe to a special service of the Agency, and men with the latest "Reuter" were always centres of much attention in exciting times. The price of Reuter's £10 ordinary charge is nominally about 5, but they seldom change hands

nowadays.

Staffordshire Worcestershire and Shropshire, Electric Power Co.—At an extraordinary general meeting to be held on May 3rd, resolutions are to be submitted for the following purposes, says the Financial Times: -

⁽¹⁾ Dividing each of the existing £5 shares into shares of £1 each, so that the share capital will consist of 900 000 ordinary shares of £1 each, of which 900 000 shares have been issued and fully-paid up; (3) converting 150,000 unissued ordinary shares of £1 each into 150,000 preference shares of £1 each entitled to a cumulative dividend of 6 per cent, and to priority for eapital without further participation: and (3) authorising the borrowing on mortgage of an amount not exceeding £100,000.

#### EXPORTS AND IMPORTS OF ELECTRICAL GOODS DURING MARCH, 1915,

THE returns of electrical export and import business for March show a satisfactory state of affairs from the British manufacturers' point of view.

Thus the exports for the month reached a total value of £391 850, as compared with £256,519 in the previous month, and £364 562 in January.

The imports of electrical material, on the other hand, have gradually fallen off since January, the March total being £203,759, as against £217,500 in the previous month. The re-exports dropped from £22,216 in February to only £8,297 in the month under review.

As regards exports from this country, the improvement in value

As regards exports from this country, the improvement in value seems to have been general, but the telegraphic and machinery

sections in particular show considerable increases, the lamp sections remaining practically stationary, and carbon exports showing a decline.

Machinery and lamp imports showed a considerable falling off, while cable and telegraphic imports were higher. Imports of electrical material from the United States have been steadily falling off since January, and only reached £129,381 in value in the month under review. Dutch imports—principally lampe—remained at a high level, and French, Italian, and particularly Swies imports, increased considerably in value in March.

The most prominent purchasers of electrical material from this country were Japan, India, New South Wales and France.

Registered Exports of British and Irish Electrical Goods from the United Kingdom.

TOTAL EXPORTS: £391.850

TOTAL RE-EXPORTS: £8.297

TOTAL IMPORTS: £203.759

NOTE.—The amounts appearing under the several headings are classified according to the Customs returns. The first and third column contains many amounts relating to "goods" otherwise unclassified, the latter, doubtless, consisting of similar materials to those appearing in adjacent columns. Imports are credited to the country whence consigned, which is not necessarily the country of origin.

#### REVIEWS.

American Electricians' Handbook: a Reference Book for Practical Lectrical Workers. Compiled by TEBRELL CROFT. London: Hill Publishing Co. Price 12s. 6d. net.

The handlook now before us is of what is known as "pocket size," though few will be found to carry such books with them as a habit. It can be put into the pocket when it is desired to take the book on to a job, and we suppose that must be the meaning of the expression.

It consists of six sections, running into 709 pages, of which 19 double-column pages are devoted to the index. This is a good feature, as a complete index is one of the most important parts of a work of reference, such as this book announces itself to be. There are 792 illustrations.

The first section deals with fundamentals, and it is possible that this part of the book is unnecessarily elaborate. Our readers will acquit us of any tendency to belittle the importance of theoretical knowledge to the practical electrical worker for whom the book is designed, but the exposition of somewhat strained hydraulic analogies is of very little value. The inclusion of 36 pages on the properties and splicing of conductors under "fundamentals" is surely an example of extreme latitude as to the meaning of the word.

Some of the definitions given in this section of the book do not fit in with what, in our time, was generally taught in English technical colleges. One example will suffice. Resistivity is the resistance of a centimetre cube of a metal, and is the same as specific resistance. Mr. Croft says that the resistance of a circular mil-foot is often called the resistivity. We do not think it advisable that authors should give meanings of their own to words already in use, although

Humpty Dumpty did so in "Alice in Wonderland."

The spelling of "coulomb" as "columb" throughout is

probably due to the author's patriotism.

The second section deals with generators and motors, and will be of considerable use to practical men engaged in the

installation or repair of this class of machinery.

The third section discusses outside distribution, and the fourth, interior wiring. As in most American books, considerable space is devoted to overhead construction and pole lines, and many useful tables, illustrations and details are given of the apparatus and accessories required in this work. Underground mains also receive a fair share of attention, and it will be found that all the more generally used systems are discussed. In the interior wiring section we are given a list of the standard symbols adopted by the National Contractors' Association and the American Institute of Architects. These seem very useful, and are calculated to save time and to render diagrams and plans more easily understood. We think some such system of conventional signs might well be adopted in this country.

We do not find any consideration of the earthing of metal conduit. It would be well if, in a future edition, instructions were given as to how to make the conduit electrically continuous, and how to earth it, with reasons why, in certain cases, this course is advisable. The suggestion as to an emergency or burglar circuit on page 518 is

interesting, being seldom if ever met with here.

Reference is made on page 537 to bell-ringing transformers, and the author says: "A bell-ringing transformer meter, a good one, will last for ever." We are not quite sure what is meant by this. So far as we know there is only one alternating-current meter which combines a transformer for bells with its normal functions. This is of a Continental type, and when introduced into Great Britain did not seem to fill any felt want. Further, it is scarcely in the hands of the consumer or his contractor to choose what meter shall be put in. That is the business of the supply authority.

Transformers are dealt with in Sec. 5, and persons dealing with such apparatus will find much assistance from it. We may remark, in passing, that in fig. 48, page 631, a sash-pot is shown. This should presumably be dashpot. As in the earlier section on outside distribution, much attention is given to overhead work and the fixing of trans-

formers on poles.

The sixth and last section deals with illumination, but tells us nothing new. We are rather glad to see that the system

of indirect lighting is not laboured so much as has been the tendency in recent years. A little diffusion is very pleasant, but too much of it is very trying.

The compilation of such a handbook is a matter of considerable labour, and, on the whole, the author has performed

American Handbook for Electrical Engineers. By HAROLD PENDER, Editor-in-Chief. London: Chapman & Hall, Ltd. Price 21s. net.

A handbook is presumably a cross between a pocket-book and an encyclopædia. At any rate, such is the impression one naturally receives at a first glance through the It contains more than 2.000 pages of present work. closely-printed matter, and, as a reference book for practising engineers and students of engineering. exceeds, with regard to quantity of material, anything we have hitherto come across Its editor-in-chief is Professor of Electrical Engineering at the University of Pennsylvania, and he has had associated with him 26 assistant and associate editors, all experts in the various branches of which they treat. Nor does the book confine itself to electrical engineering only, for it includes a great mass of data on those mechanical and civil details which are in any way related to the electrical, and with which up-to-date electrical engineers

would be expected to keep in touch.

The work, in addition to being remarkable for the great quantity of matter it contains, has several novel features incorporated with it. As the book is primarily intended for the practising engineer, all theoretical discussions have been segregated into separate articles, and only sufficient theory is given in subjects dealing with practical matters to render Numerous mathematical tables and the context plain. relations are given, among which may be mentioned articles on logarithms, trigonometric functions, hyperbolic functions, exponential functions, derivatives, integrals, indeterminate forms and equations. The matter is arranged in encyclopadic fashion; that is, the articles are taken in alphabetical order, an arrangement which appears to us eminently reasonable in consideration of the vast quantity of data presented. One plan of treatment has been followed wherever possible, the method especially applying to articles dealing with apparatus and machinery, as follows: - (a) General description and definitions; (b) brief statement of application; (c) principle of operation; (d) design; (e) testing; (f) performance; (g) specifications; (h) installation; (i) operation; (j) dimensions, weights and costs; (k) bibliograpby.

Cost data have received much attention, and the editor very justly points out in this connection that students and recent technical graduates are sadly lacking in even the roughest idea of the price of apparatus and structures; it is chiefly to supply a rough idea of such costs that the cost curves and figures are given wherever possible. it is the hope of those who have compiled the volume that teachers in technical schools may find many of the articles suitable as bases for courses of lectures. We are inclined to think that this desire has been successfully achieved, more especially in the electrical than in the mechanical and civil departments, and that teachers will find the book of great help in preparing lessons which will contain the gist of the matter under consideration uninvolved by cloying masses of by-products. The bibliography at the end of each article is also very useful, but it is only intended to direct the reader to more extended information in treatises and current periodicals and does not make any pretence to

completeness.

The preparation of the volume has occupied approximately three years, and none of the plates were cast until the summer of 1914. Before casting, all the galleys were revised, and in some instances large sections of the articles were re-written.

Such a work, involving as it does a tremendous amount of labour and care, it were almost invidious to The perfect condensing down of subjects interconnected like those of engineering, so that nothing essential is omitted and nothing superfluous admitted, is a task at which the superman might very reasonably quail. And it is going far to say that this condensing down has been generally done, in the present case, with method and

The brevities of the pocket-book and the verbosities of the text-book have both been evaded, and the result is something that has real and lasting value. Perhaps under the title of Electron Theory a little more might have been given, as this particular subject appears to us, especially in view of its comparative newness undoubted importance for the future, to and its have been unduly condensed. Likewise, u der the headings Steam and Thermodynamics, a little fuller explanation might have been supplied regarding entropy and its applications and the entropy chart in general, and perhaps a few typical problems might have been briefly worked out. But these are details which detract little from the value of the work as a whole. The handbook is well worth its price, though the purchaser, of course, has to remember that it is written from the American point of view and agreeable to the practice of that country.—W. J. C.

Laboratory Course in Electrochemistry. By OLIVER P. WATTS. 1914. London: Hill Publishing Co. 4s. 2d. net.

This small volume of practical methods of electrochemistry forms a very u-eful addition to the ever-increasing bulk of this branch of Science. It is intended for students who have access to an up-to-date laboratory equipment, and for use as a supplement to explanatory text-books. The author opens with a short preface, in which he states that the manual has been designed primarily for his classes in the University of Wisconsin, but he hopes that it will also be of use elsewhere. The introduction contains a short account of the necessary laboratory equipment, based on the apparatus at the disposal of the author. This description. although interesting, is too brief to be of great utility.

Many useful hints are contained in this section of the book, but its undoubted value is impaired by lack of The author then continues with the usual stock detail. instructions to students, which are admittedly beneficial when carried out.

The experimental part of the book is introduced after this This section constitutes the chief feature of the manual, and contains 133 selected experiments. is clearly and simply described, but no explanation of the expected result is given, although apposite questions are asked to test the student's comprehension of his subject. It is clear, therefore, that this manual is intended chiefly for students working under tuition, its main object being to induce a careful analysis of the results.

The first experiments illustrate the phenomena accompanying the electrolysis of aqueous solutions, which naturally include the resistivity of electrolytes and errors due to polarisation. Faraday's law is clearly elucidated, and is polarisation. followed by a demonstration of the use of coulombmeters.

The next pages are devoted to the measurement of electromotive force, and in this section the author describes a very simple and cheap form of potentiometer, which is well Experiments illustrating the phenomena worth copying. of over-voltage and passivity are included here.

The corrosion of metals is next dealt with, preciding a description of the separation of metals from alloys and com-There is also a very brief account of plex solutions. electrochemical methods of analysis, but this is intentionally incomplete.

A considerable section of the book is devoted to electroplating, and the electro eposition of pure metals and alloys. There are also numerous recipes for the colouring of metals. These are without doubt of great interest, but scarcely come within the scope of a manual devoted to electrochemistry.

The concluding experiments describe the preparation of a few inorganic compounds. The book closes with an appendix The experime ts are copiously of tables and an index. illustrated with diagrams and curves. The treatment is simple but clear throughout, and the book undoubtedly forms a very useful addition to our electrochemical literature, and may be recommended with confidence to all students desiring a general knowledge of practical electrochemistry.

#### MAIN-LINE SIGNALLING ON RAILWAYS.

By W. C. ACFIELD.

(Abstract of paper read before the Institution of Electrical Engineers at Birmingham, March 31st, 1915.)

(Concluded from page 567.)

Concluded from page 567.)

Semi-automatic signalling.—This term denotes a manual system of control in combination with an automatic signalling system, by which signals placed beyond the limits of ordinary working are controlled partly from a signal-box and partly by track-circuited lines. It is used for splitting up long block sections, the control from the signal-box enabling the custemary "normal danger" system to be maintained on steam-operated railways. The portion of the line between the starting or advance signals of the rear and the home signal of the advance sections is divided up, and the semi-automatic stop and distant signals are placed in the most suitable positions to suit the gradients. There are two ways of dealing with the problem, viz.:—

problem, viz.:—
(a) By making the semi-automatic signal act as an advance

(a) By making the semi-automatic signal act as an advance signal to the rear section, in which case ordinary block working is maintained.

(b) By making the semi-automatic signal act as an outer home signal to the advance section (see fig.4), in which case the ordinary block system between the rear and advance signal-boxes is dispensed with and the traffic is worked by bell codesignals.

signal-boxes is dispensed with and the traffic is worked by bell code-signals.

The latter system has certain advantages over the former, inasmuch as a train entering the semi-automatic area is more under control of the advance signalman, because, in the case of a train over-running signals, the advance signalman has the opportunity of stopping the train by placing detonators on the line in cases of emergency. Moreover, a bell code is more convenient than a block system. In either system the track circuits are divided up, and in order to comply with the standard clearance regulation the usual overlap of a quarter of a mile is provided to all signals in the semi-automatic area, the signals being replaced to danger upon the train leaving a track-circuited section. a track-circuited section.

It is not advisable to work semi-automatic signals a long distance from signal-boxes on account of the difficulty in regulating wires affected by temperature variations; the signals are therefore worked by motors, controlled by switches on the levers in the signal-boxes.

Fig. 5 shows the form of track indicators for semi-automatic signalling, as used on the Midland Railway. In semi-automatic signals such as those described, a difficulty must arise in foggy weather in getting fog-men to the distant signals, and in order to safeguard against such conditions instructions are issued that semi-automatic signals must not be relied upon, but more are not generally used to enforce the intervations. but means are not generally used to enforce the instructions. The case can, however, be met, with small extra expense, by providing what is termed a fog lever in the signal-box in advance, which upon being pulled over links up the various track-circuited sections as one long section and renders it compulsory for the signalman to lower the semi-automatic signals before the starting signal in the rear can be lowered for a train to love that section train to leave that section.

The term semi-automatic is also applied to signals of auto-

matic-signalling installations where there are crossover roads or connections with sidings worked manually or by power from a signal-box; but so long as the points are not used the

from a signal-box; but so long as the points are not used the signals continue to be operated by the passing of trains over the track-circuited lines.

This arrangement is very flexible in working and can be adapted to manual interlocking frames of the ordinary pattern, the points being operated by rodding as usual and the signals electrically, the signal lever when reversed closing a contact in the signal circuit. The signal circuits are so arranged that when it is unnecessary to operate the points, the signal levers may be and are generally left in the reverse position; the signal control is then governed solely by the track-circuited lines to which the signals apply and becomes entirely automatic, thus enabling block or lock-and-block instruments to be dispensed with. This has the merit of enabling existing signal-boxes and locking frames to be retained, where necessity arises, when installing automatic signalling on steam or electrified lines, and very considerably reduces the cost of installation, as against "scrapping" existing locking frames and providing power frames working points. It thus places and providing power frames working points. It thus places the reconstruction of signalling systems within reasonable reach of railway companies at a comparatively lower cost.

Automatic signalling.—The object to be attained by the use of automatic signal being put to danger behind each train on a double line of railway, and cause it to remain in that position until the train has gone a certain distance beyond that signal. In the case of single lines the same object is attained, with the addition that at all times a signal governing movements in the direction opposite to that in which the train is moving must be displayed in the danger position some distance ahead of the train.

Automatic signalling is an admirable substitute for the

Automatic signalling is an admirable substitute for the Automatic signaling is an admirable substitute for the block system, the signal movements being governed by electric or pneumatic agency, controlled by the passage of a train into, through, and out of the block section to which the signals apply; this is effected by the action of the train alone

operating the track-circuited sections of the lines controlling such signals, the ideal arrangement of automatic signals being such as to secure the maximum capacity for train movements over a given length of line, bearing in mind the effect of gradients and curves on the traffic. Two systems of automatic signalling are used, viz. :-

(a) Normally danger.(b) Normally clear.

The normally danger system, in which the signal stands continually at danger except when trains are required to pass along the line, agrees with the normal position of a mechanical or manual system, and complies with the standard practice of the block regulations as laid down for traffic working. After being placed to danger by the train entering the section, the signals remain in that position until they require lowering for the following train, this being done by the approaching train lowering the signals if the section ahead is not occupied for traffic in the same direction. This system necessitates greater complications in the electrical connections, as the track circuits have to be so arranged as to lower the signals in addition to replacing them to danger.

In normally clear systems the entering of a train into the track-circuited section places the signal in the rear to danger, and the clearing of the block section, by the passage of the rear wheels of the train out of it, resets that signal to the The normally danger system, in which the signal stands

There are many advantages in power-working as against other methods, as several sets of points can, if necessary, be operated by one lever, and more than one signal can be operated per lever by the aid of a selector arrangement, so that on the whole the total number of working levers can be

very materially reduced.

There is a further advantage attained in relation to facing points, as the Board of Trade requirements in regard to the maximum distance for working the same by power have been relaxed, this distance being extended to 300 yards from the signal-box. This concession alone is most helpful in the laying out and planning of works, and thus recommends itself to

railway engineers.

The essential features of a power system are that the operation of all points and signals, etc., must be ensured, and that the possibility of any movement not being completed must be

guarded against.

In power systems the locking in one direction must be counter-locked in the other direction. For instance, the fact of releasing a bolt lock on a ground frame does not prevent the lever effecting the release being replaced; and therefore the lever in the ground frame thus released and working the points must in a like manner operate a back-lock on the lever in the interest have better the property of the lever in the counter of the lever in the counter of the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in the lever in signal-box. Detection of signals and points is, however, easier and more elastic than in manual systems on account of the absence of the regulation of wire connections, and lends itself

FIG. 5.—TRACK CIRCUIT INDICATOR.

clear position, ready for a following train in the same direction to approach. Those in favour of this system contend that the electrical connections are fewer and more simple, and from a maintenance point of view less costly. There is much to be said in favour of the normally clear system, because, after all, automatic signals differ considerably from mechanical or manual systems, as they simply indicate to drivers that the section or sections ahead are clear and are an indication of the condition of the line ahead.

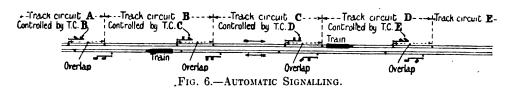

In all automatic-signalling installations there is the risk of

FIG. 4.—SEMI-AUTOMATIC SIGNALLING.

In all automatic-signalling installations there is the risk of trains being unduly delayed at signals in the event of failure of the apparatus, in which case the signal would remain at danger. To provide against such a contingency it is customary to allow drivers to pass the signal in the danger

to overcome many difficulties experienced in the manual system.

A large number of signal-boxes have been installed in Eng-A large number of signal-boxes have been installed in ling-land, and the largest installation is stated to be that at the Glasgow Central Station of the Caledonian Railway. It consists of 338 working levers controlling 112 points and 245 signals, and has proved its value. The levers in the locking frame, after being moved sufficiently far to operate the points, cannot be moved completely over, owing to a stop termed a "check lock," which is electrically removed when the points have gone properly over, after which the lever is free to be moved over completely. The mechanical locking of the tappet type then allows the necessary signal levers to be pulled over. type then allows the necessary signal levers to be pulled over If for some reason due to the points not working properly, the

position after coming to a stand and waiting a prescribed time, as laid down in the rules and regulations of working. After starting again the driver is allowed to proceed cautiously, being prepared to stop at or before reaching the next signal. If the next signal is at clear he may proceed at regular speed until reaching the next signal at danger.

Fig. 6 shows an arrangement of automatic signals for one road on a double line of railway. Single lines of railway can be worked by means of automatic signalling instead of by train staff or tablet systems, but up to the present the author is not aware that such an arrangement is in use in this country.

country.

Overlaps.—These consist of an extension of a track circuit from 100 to 440 yards ahead of a signal, such track circuit and its extension, when occupied, securing the signal in the rear

Overlaps are used to guarantee that a space is provided between one train, standing at or passing a signal, and another train in the rear—instead of relying on the thickness of a signal post to give protection—and comply with the regulation that a second train must not be allowed to approach the rear signal until the preceding train has passed at least a quarter of a mile beyond the governing signal. Thus the track circuit between two signals extends ahead of the signal, from 100 yards to 440 yards the length being regulated to from 100 yards to 440 yards, the length being regulated to suit the gradients, speeds, and curves of the railways, whether steam or electrified working is in operation.

steam or electrified working is in operation.

Power signalling.—This is a means of operating an interlocking system of points and signals by some form of power
other than manual, in which levers for moving points or
signals by levers, rods, and wires, are supplanted by levers or
slides which close or open valves or electric circuits. The
levers or slides are small and are placed close together, so that
the length of locking frames and signal-boxes is at once
reduced, and they can be placed in confined places, without
disturbing the lay-out of the roads in large stations or yards.

point lever cannot be moved right over, the signals for the particular route cannot be lowered. A somewhat similar arrangement is provided on the points, and compels the signal being properly placed to danger before the signal lever can be restored completely to its normal position. The signalman is thus advised of any failure due to the signal not going to danger, and locks up the apparatus so that further movements are impossible.

are impossible.

The mechanism for operating the points is placed outside the 4-ft. way, and consists of an escapement bell crank, the plain end being connected to the stretcher rod of the points, and the escapement end operated by means of a slide with a projection or roller connected to the piston rod. Air is admitted to the cylinder at one or the other end and gives the necessary movement to the slide operating the bell crank, which is also connected to the locking bar. The total movement of the slide produces three distinct movements of the mechanism: first, the locking bar is lifted; secondly, the points are moved; and thirdly, the locking bar is lowered. It therefore follows that if any wheels are on the locking bar the points cannot be moved. points cannot be moved.

the points cannot be moved.

Electrical detectors are connected to the tongues of the points, thus ensuring that the points are completely set in one direction or the other, and they indicate to the signalman that the points are properly over, by the clearing of the stop on the previously mentioned lever in the signal-box. The operation of signals is somewhat on the same lines, air being admitted into one end of the working cylinder by means of pin valves operated by electro-magnets.

In electro-pneumatic installations where the lines are track-circuited, illuminated diagrams are installed instead of the

circuited, illuminated diagrams are installed instead of the signal-box diagrams usually provided. The roads, points, and signals are exhibited on glass which is opaque all over except the roads. Electric lamps are placed behind the roads in the diagram, and are partitioned off in lengths to correspond with the track-circuited sections, and are so controlled by the track-

circuit relays as to be always alight, except when the circuit is opened owing to the presence of a train in the section. When the lights go out the signalman is advised, by the darkened portion of the roads, that the section is occupied. By this means the signalmen in the signal-boxes from which the points (or signals in some cases) cannot be seen, are able to perform their duties, and are yet able to cope with the traffic although the latter is practically hidden from view. It also enables the signals and points to be manipulated with remarkable rapidity.

able rapidity.

All-electric systems.—In view of the perfected electric motors

enables the signals and points to be manipulated with remarkable rapidity.

All-electric systems.—In view of the perfected electric motors now in use, and the fact that only one kind of power is desirable, this system recommends itself to the signalling world generally. The point mechanism in all cases is operated by motors, and the signals by motors in some types and solenoids in others; but the general tendency is to use motors for all purposes.

There has been a great deal of discussion as to the use of "check-lock, as previously described, prevents the signalman pulling the lever in the signal-box completely over, or restoring the same until the return-indication has removed the lock on the lever, whereas in constant-detection the lever can be pulled completely over without having to wait for the return-indication. This alone must expedite the signalman's movements and enable the work to be done with greater rapidity. The constant-detection breaks down all signal circuits from the moment the lever in the signal-box is moved from one position to the other until the points have been properly operated, and should any points be moved or interfered with by accident or design, the signal circuits affected by the position of the points cause the signals to go to danger, if off, or to be held at danger as the case may be.

A great advantage of the constant-detection principle, although the system is perhaps more costly in installation, is that it enables a failure of detectors to be easily located, and thus saves much running about on the part of the signal fitters and consequent loss of time. From experience of others it may be contended that this method is preferable, as most troubles can be located in the lever frame in the signal-box instead of having to be sought for on the ground. This perhaps will appeal generally as one of the vital points of power signalling, as electricity is doubtless the coming motive power for operating points and signals.

All-electric system with dynamic indication.—This interlocking

The stroke of the lever is divided into two movements. The first movement locks all conflicting levers and operates the point mechanism; but in the second and final movement the stroke of the lever can only be completed when the point mechanism has done its work in operating the points. This final movement can be made after, and only after, the dynamic indication has been received certifying that the operated function has assumed a position corresponding with that of the lever in the signal-box.

When the points are to be operated the first movement of the stroke of the lever in the signal-box permits current to flow to the motor, thereby causing the mechanism to move the points to the opposite position and lock them in that position. When this movement has been completed, the circuit through the switch motor is automatically changed, the motor being disconnected from the battery and connected in a closed circuit including the indication magnet. At the same time the armature terminals are reversed for indication purposes, this leaving the motor connections in the proper position for the armature terminals are reversed for indication purposes, this leaving the motor connections in the proper position for the next operation. The motor now becomes a dynamo, and with the momentum acquired during the operation of the point movement generates a momentary current which energises the indication magnet, this permitting the final movement of the lever in the signal-box to be completed, releasing such levers hitherto locked. The movement of the points can be reversed at any portion of the travel by the operator at will, and the lever movement completed upon the points assuming a position corresponding with that of the lever, irrespective of the direction of the first movement made by the lever. made by the lever.

The complete point operation, and the final movement of the lever, can be accomplished in from 2 to 24 seconds, the indication being practically instantaneous with the completion

The indication that the points have moved correctly is given by a current generated by the momentum of the motor, and can therefore be obtained only after the actual operation of the point mechanism, no additional power being required for the indication that the points are properly set to allow of the required signals being lowered to give permission for a train to proceed. to proceed.

#### DISCUSSION.

Mr. A. Hurst (President of the Institution of Signal Engineers), in opening the discussion, explained a fundamental difficulty of designing signal apparatus which was due to the necessity of making it comply with conflicting conditions. When high and low speed traffic passed over the same rails,

the signalling must be suited to the requirements of the highspeed traffic, and this was not always the most suitable for low-speed traffic. Ideally, two distinct systems of signalling were required to suit the two cases, but this was not practical, were required to suit the two cases, but this was not practical, and in consequence the design of signal systems resolved itself into finding the best compromise. With regard to electrical apparatus, the engineer must not think that because his apparatus worked well in the laboratory it would also work well on the road, because disturbing factors were often found in practice which were not suspected until failure was experienced under actual working conditions. As an instance of this kind of thing, he mentioned that if the engineer in repairing a line put in a new length of rail, the electric signalling apparatus ceased to operate until the skin of the rail had been removed.

Mr. A. F. Bound mentioned that in all-electric signalling one unit of energy would operate from 500 to 600 signals.

Dr. Kapp demonstrated a model of the Railophone method of signalling and explained the operation of the Kapp-Kramer relay.

signalling and explained the speak of that enthusiasts for power signalling schemes fell into the error of supposing that men could be reduced to a negligible quantity and the speed of working vastly increased. The electro-mechanical system now being extensively adopted in the U.S.A. enable many of the advantages of power signalling to be obtained without the troubles of maintenance and operation that were liable to attach to power-worked points.

the troubles of maintenance and operation that were liable to attach to power-worked points.

Mr. W. J. Thorrowcood (communicated) stated that the advantages of track circuits were obvious, and no doubt extensive use would be made of them in future. The weak spot was the fact that there were a number of vehicles fitted with Mansell wheels (i.e., wooden block wheels). Such wheels failed to operate the track circuit apparatus. The difficulty could be overcome by bonding the hub to the rim. The use of sand by drivers should be discouraged, as the accumulation of sand on the rail was likely to introduce considerable resistance between the rail and rim of the wheel and thus cause even a heavy engine to fail to operate a track circuit.

TATTERSALL (communicated) stated that in his Mr. A. E. Tattersall (communicated) stated that in his opinion the alternating-current system would eventually supplant the direct-current in track circuiting in this country, especially in large installations, for the following reasons (1) It afforded an economical system of power transmission, and the main could be utilised for other purposes than signalling, such as power and lighting; (2) the question of track insulation did not enter to nearly such a large extent as in direct-current systems; (3) extraneous currents could be fully guarded against by using suitable frequency relays or employing some form of apparatus embodying the principle of resonance. resonance

Mr. WHYSALL (communicated), in referring to the author's Mr. WHYALL (communicated), in referring to the author's statement as to the debatability of a signalman being able to attend to more roads under power systems than under manual signals, referred to the fact that during the rush hours on the District Railway 98 trains per hour were passed through Earl's Court Station. There were four roads through this station. All these trains were signalled by one man operating a power frame. A signalman doing the same work with a manual frame would be exhausted towards the end of his shift.

#### TRADE STATISTICS OF SIAM.

The following figures, showing the imports of electrical and similar goods into the port of Bangkok during the year ended March, 1914, are taken from the recently issued official trade statistics: the figures for the year ended March, 1913, are included for purposes of comparison and notes of any increases or decreases are given. Imports stated to be from Singapore and Hong Kong are for the most part the products of other countries shipped via these two ports.

#### TRAIN DISPATCHING BY WIRELESS.

In a paper on "Train Dispatching by Wireless," read at the New York Railroad Club, on February 19th, by Mr. L. B. Foley, superintendent of telegraph, telephone and wireless, Lackawanna Railroad, New York, the following statements were made:

were made:—

"The wireless apparatus aboard the train is of one kilowatt rating, and similar in principle and operation to that at the fixed stations. The motor-generator on the train is operated on thirty volts direct current from the car-lighting generator, which carries on its line a set of storage cells. This motor-generator draws about forty amperes, and provides 500-cycle alternating current at 250 volts for the radio transmitter, including a ten-unit quenching gap, three glass-jar condensers of .002 microfarad each, and the usual radio frequency transformers. The antenna current is about thirty-five amperes.

formers. The antenna current is about thirty-five amperes. "We can communicate from a moving train to a fixed station a distance of 130 miles. Owing to the low antenna of the passenger cars, we have not as yet been able to transmit a greater distance from the train, but are able to receive messages on the train from a fixed station at a distance of 200 miles. On the train the aerial or antenna is formed of phosphor-bronze wire arranged in four rectangles, one on the roof of each of the four forward cars lengthwise, with an additional wire lengthwise, and all parallel with the top of the car, each rectangle being carried on porcelain insulators at the corners and centre of each car, with wire link connections between the cars. The wires clear the top of the cars about eighteen inches, being low on account of bridges and overhead interferences; therefore the radiating power is limited. The lead is taken from the middle of the train antenna through the inside of the car, near the roof, into a compartment two by four feet, which contains the wireless telegraph apparatus and the operator.

The required voltage was obtained from the train-lighting system, and after the first trip on the train it was found that the operation of the train installation did not in any way interfere with the track signals. The speed of the train, or its change of direction while en route, does not have any effect on the transmission or reception of signals, and communication to and from the train is not retarded while the train is passing through tunnels

through tunnels.

"The train radio service has been used for various purposes, such as reporting the number of passengers on board destined to connecting lines, for providing additional cars, or cutting out cars at divisional points, or ordering an ambulance at next train stop for persons taken ill on the train. Commercial telegrams for passengers are handled. In one instance a telegram was filed by a passenger on the train for a resident in the city of Scranton, the message transmitted to destination, delivered, and the reply received by the sender in twenty minutes.

minutes.

"The wireless telegraph can be depended on between fixed stations, and between moving trains and fixed stations. There are many uses for the wireless telegraph in railroad train operation. It enables the dispatcher to communicate direct with the train, and train orders can be transmitted as accurately and reliably as by telegraph or telephone. The wireless, together with a selective device, can also be used for setting signals at distant points.

signals at distant points.

"The wireless telegraph serves as an auxiliary method of communication, in addition to the telegraph and telephone, in the event of interruption to wire facilities, and has already proved its practicability and efficiency under such conditions.

not only between fixed stations, but also between a moving train and fixed stations, and the results obtained by the Lackawanna during the past year have been valuable in many ways. It is the company's intention to extend the service over

ways. It is the company's intention to extend the service over the entire system.

"We have not found it necessary to go outside of our own organisation to obtain operators that can handle wireless equipment and wireless messages. Our wireless office at each divisional point is located within a few feet of the dispatcher's office; and in the event of total wire failures on any part of the road, the wireless is immediately resorted to, operators at divisional headquarters being instructed to listen for a period of five minutes, and if no one is calling, then to call the nearest wireless station for a period of five minutes. This results in the various stations getting into communication with each other in a very few moments. We no longer fear sleet storms, which are becoming more frequent, and which annihilate pole lines of the strongest construction.

"The fact that we are obliged to carry a telegraph operator

"The fact that we are obliged to carry a telegraph operator on each train equipped with wireless telegraphy, or employ a trainman that is a telegrapher, led us to take up the development of the wireless telephone. We have obtained some favourable results, having talked from a fixed station to a moving train a distance of fifty-three miles."—Telegraph and

Telephone Age.

[The Lackawanna installations were described in our issue of March 20th, 1914.—Eds. Elec. Rev.]

#### EUROPEAN MARKETS FOR ELECTRICAL SUPPLIES.

The following are extracts from certain reports which have recently been collected by the American Government from Consular Officers in various centres for the benefit of the electrical manufacturing firms in the United States. The main

Consular Officers in various centres for the benefit of the electrical manufacturing firms in the United States. The main portions of these reports have not been published, but are being reserved for inspection by American firms.

GREECE (SALONICA).—Recent political changes which have brought Macedonia under the control of a people imbued with progressive ideas constitute a factor favourable to the extension of trade in modern technical appliances of all kinds. Salonica, the commercial centre of Macedonia, is the only city in the Province which at present has an electrical plant. Current is generated by three crude oil engine sets, which have a current-producing capacity of 2,400 H.P.

A Belgian company operates the local power plant, as well as the trainway and municipal lighting systems. (The cars used on the tramway were built by a well-known American concern.) In the past nearly all of the company's electrical supplies have been imported from Belgium. As the trade of that country is now paralysed, it would seem an opportune time for manufacturers to place themselves in communication with this firm. In Salonica electricity is used less than other agents for illuminating purposes, candles, petroleum, and gas predominating. There can be noticed, however, a steady increase in the employment of modern methods of lighting; shops, cafés, hotels, and some of the newer residences have electrical installations, and a slight gain is evident in the use of electric bells and private telephones. Salonica has no public telephone service: it is thought gain is evident in the use of electric bells and private tele-phones. Salonica has no public telephone service; it is thought that if such service is installed it will probably be undertaken phones. Salonica has no public telephone service; it is thought that if such service is installed it will probably be undertaken either by the Government or under strict Government supervision. The European war has brought all local construction work to a standstill, and until more normal conditions prevail there will be little opportunity for large sales of electrical materials in this district. This state of affairs, however, should not deter manufacturers from taking an immediate interest in this market and from bringing their products to the attention of the prospective buyers. Entering into consideration are telephones and all construction materials, wire and cable, are lights, electric lamps, ceiling, wall, and stand fixtures of inexpensive material, wiring supplies, bell systems, annunciators, and novelties, constructed for a minimum of 220 volts, direct current. Local dealers in electrical materials have imported in the past from Germany, Belgium, and Austria-Hungary, but are willing to purchase from America provided the terms offered are as favourable as those of European manufacturers. No special electrical apparatus is in demand here, but some dealers have expressed a desire to place upon this market a line of electrical novelties, such as curling irons, toasters, bot plates, and sadirons, all of which are not well introduced as yet. A concession has been granted recently to a group of English capitalists to construct an electric plant capable of developing 60,000 candle-power at Cavella, the Macedonian city, ranking next to Salonica in importance. The plant is to be owned and operated by the company, but the municipality reserves the right to purchase the installation at any time after ten years' operation.

The religious community of Mount Athos, Macedonia, is contemplating giving a franchise to a Greek syndicate to install an electric light plant at that place. Still another town in Macedonia is considering the erection of an electric light and power plant, but the plans therefor have not yet matu

a small scale by simple hydraulic power. It has been estimated a small scale by simple hydraulic power. It has been estimated by engineers that waterfalls in Macedonia are capable of producing a total hydraulic force of 20,000 H.P., while only 4,140 H.P. are now being used. When economic and political conditions in the country are demnitely adjusted the hydraulic energy now going to waste will doubtless be directed into commercial channels. Most of the mill-owners are not now inclined to install electrical machinery, which, they claim, is unnecessary and expensive. One or two millers, however, have expressed the opinion that hydro-electric machinery could be proposably contemplating the have expressed the opinion that hydro-electric machinery could be prontably employed. Firms seriously contemplating the introduction of electrical goods in this district could not do better than send thoroughly competent representatives, who speak French, to consider the situation at first-hand. The next best method of entering this market is through correspondence, descriptive literature, etc., in French. Importers prefer quotations c.i.f. Salonica. Under normal conditions terms would be part-cash with order—sufficient to cover freight and expenses—and the balance cash against documents on arrival of merchandise. of merchandise.

SCOTLAND (GLASGOW).—There is at present an unusual opportunity for the sale of electrical scientific instruments in Glasgow, due to the fact that in the past nearly all such instruments were imported from the Continent. The same may be ments were imported from the Continent. The same may be said of tungsten filament lamps which, prior to the war, came principally from Germany and Austria. The supply of tungsten on hand is said to be all but exhausted. Another product that is affected by present conditions, and one that offers American manufacturers an excellent opening, is the arc light carbon electrode. Owing to the elimination of Continental competition, the local selling price of carbons has risen 175 per cent. There is only one firm manufacturing carbons in this country at present, and the Government has first claim on its output. The carbon that had the largest sale before the war was the product of an Austro-German firm. This electrode was very popular for all purposes, and little other was used in this country owing to its low price. American carbons, it is said, have not been well regarded here. They are reported to be good and bad in parts, like an imperfect pencil, so that the arc lamp burns satisfactorily until a bad section of the electrode is encountered, when the light splutters and goes out. A satisfactory carbon at a fair price will always find a profitable market here. profitable market here.

profitable market here.

SPAIN (MADRID).—There is in Madrid a strong demand for electrical goods, accessories and supplies of all kinds, and it is believed that practically every article in this line can be sold here—but not on the terms usually asked by American exporters. The Spanish merchant has been accustomed to at least 90 days, and he will not trade on any other basis. For example, a Madrid concern recently sent its representative to the American Consulate relative to a transaction in electrical supplies that had been started by this office, and which involved a fairly large amount. The entire negotiation fell through because of the American exporter's insistence for cash against documents. The Madrid merchant stated to the Consul that he still had some German stock on hand; that he would use it until it was exhausted; and that he would then close his shop until the war was over and Germany again entered the market. This attitude is general in the Madrid district.

SPAIN (ALMERIA) —A canvass of the leading dealers in

SPAIN (ALMERIA).—A canvass of the leading dealers in electric light accessories at Almeria discloses the fact that, stand (ALMENA).—A canvass of the leading dealers in electric light accessories at Almeria discloses the fact that, although general stocks are in no way depleted as yet, such articles as bulbs, wires, wall switches, and lamp supports are not being supplied with any degree of promptness by Spanish dealers or by the foreign firms that heretofore have monopolised this trade. Almeria is a seaport of 50,000 inhabitants; it has good water communication with the other ports of Spain, but lacks direct service with the United States and some countries of Europe. The local consumption of imported articles, excepting certain classes, is insufficient to warrant direct trade therein, it being more advantageous for local merchants to order foreign-made goods from importers located at Barcelona or Madrid, who offer much more attractive terms than American exporters, and are in position to quote prices c.i.f. Almeria. The latter fact is an important consideration with the local dealers. In view of the present inability to draw all electrical supplies from the usual sources, it is believed that there is now an opportunity here for placing American goods. For the reasons already set forth it is thought that the best plan to reach this trade might be to designate a general agent in Barcelona or Madrid, whose salesmen could cover this district.

Metropolitan Association of Electric Tramway Managers.—A meeting of the members of this Association was held on the 16th inst., at the Municipal and County Club, Whiteneid on the 18th inst., at the Municipal and County Club, White-ball Court. Whiteball. S.W., when there were present Messrs. Ullmann (Rast Ham). chairman. Fell (L.C.C.) Schoffeld (L.cyton), Moffet (West Ham) Harvey (I'ford) Stokes (Bexley), Meckinnon (L.U.T.), and Goodyer (Croydon), hon. scoretary. Letters and telegrams of regret at inability to attend were received from Messrs, Brince (L.C.C.). Murray (Walthamstow), Williams (Erith), Pott and Hammond (M.E.T.), Mason (S.uth Met.), and Birkett (Southend-on-Sea). (Southend-on-Sea),

#### INDIAN NOTES.

#### [FROM OUR SPECIAL CORRESPONDENT.]

The War and Electrical Contractors.—Whether due to the consequences of the war or other causes cannot be defined, but a good few small electrical contracting firms in Bombay but a good few small electrical contracting firms in Bombay and Calcutta, and elsewhere through India, have gone bankrupt or disappeared within the last six months. Factors and commission agents at home take serious risks in doing business direct with small firms and bazaar contractors, unless their bona-fides are established beyond doubt. Even doing such business through banks is not entirely satisfactory, as very often consignments are refused and thrown back on the home buyer, who often has to dispose of his goods in India at a severe loss rather than have them returned. Now that German and Austrian goods are no longer procurable, manuat a severe loss rather than have them returned. Now that German and Austrian goods are no longer procurable, manufacturers at home may expect all sorts of inquiries from Indian "firms" of high-sounding name, but before doing any serious business it would be well to have payment in advance. These remarks apply only to comparatively small firms of short standing—there are many old-established firms whose integrity is beyond reproach, and whose business has been built up on a sound basis.

Metal Lamps.—The very unwise game of "beggar my neighbour" is being played just now by firms from whom one would expect better in connection with the sale of metal filament lamps. Three such firms have offered to deliver on rail 900 miles from Bombay or Calcutta, 40-watt 220-volt lamps at one rupee per lamp in quantities above one thousand. In the face of increased importing charges one wonders how it can be done, and if it pays.

face of increased importing charges one wonders how it can be done, and if it pays.

The Mails.—Mails to India now take, instead of the usual 14 days to Bombay, about 21 days, or even more. This is not to be wondered at, nor do people complain; in fact, considering the position in the Suez Canal and round the southern coast of England, it is surprising that we get our mails with the regularity that we do. A good many home firms make a habit of sending duplicate letters by following mails from home, which seems to be a sound practice.

Fewer Catalogues with Fuller Details Recommended.—Firms in America are inundating India with business circulars and lists, and electrical firms especially are busy in this direction. Both English and American firms make the same mis-

Both English and American firms make the same mistake in common, namely, they do not give sufficient parti-culars as to prices, discounts and deliveries. It would save money in postage and printing if fewer catalogues and lists were sent out giving better selling particulars and lowest rates to.b. home ports, or c.i.f. India, to a select number of serious firms, whose names can be found in any universal directory.

The Dominions Royal Commission.—The fourth interim report of the Rayal Commission on the natural resources, trade, &c., of the Diminions was recently issued; the Commission had reached Newfoundland and Eastern Canada when war broke out and the members were recalled, and the Commission decided to suspend its sittings until peace was concluded. The report points out that British manufacturers make no organized bid for the trade of Newfoundland and the Maritima Periods of Contract of Newfoundland and the Maritima Periods of Contract of Newfoundland and the Maritima Periods of Contract of Newfoundland and the Maritima Periods of Contract of Newfoundland and the Maritima Periods of Contract of Newfoundland and the Maritima Periods of Contract of Newfoundland and the Maritima Periods of Contract of Newfoundland and the Maritima Periods of Contract of Newfoundland and the Maritima Periods of Contract of Newfoundland and the Maritima Periods of Contract of Newfoundland and Contract of Newfoundland and Contract of Contract of Contract of Contract of Contract of Contract of Contract of Contract of Contract of Contract of Contract of Contract of Contract of Contract of Contract of Contract of Contract of Contract of Contract of Contract of Contract of Contract of Contract of Contract of Contract of Contract of Contract of Contract of Contract of Contract of Contract of Contract of Contract of Contract of Contract of Contract of Contract of Contract of Contract of Contract of Contract of Contract of Contract of Contract of Contract of Contract of Contract of Contract of Contract of Contract of Contract of Contract of Contract of Contract of Contract of Contract of Contract of Contract of Contract of Contract of Contract of Contract of Contract of Contract of Contract of Contract of Contract of Contract of Contract of Contract of Contract of Contract of Contract of Contract of Contract of Contract of Contract of Contract of Contract of Contract of Contract of Contract of Contract of Contract of Contract of Contract of Contract of Contract of Contract of Contract of the trade of Newfoundland and the Maritime Provinces of Canada, which has been largely captured by the United S ates, but could probably be recovered. The importance of Newfoundland as a cable centre is emphasized, and the report suggests that when existing concessions for landing rights come to be renewed or new ones are sought, the Colony should consult with the Governments of Canada and Australasia, as well as with the Imperial Government, before a decision is reached. A cable and landlines connecting St. John's with Canso belong to the Government of Newfoundland, and may form part of a future State-controlled route between the United Kingdom and Canada. The report states that the island enjoys excellent facilities for communication by cable at cheap rates with Great Britain and Canada, though there are certain anomalies that need rectification. There is also a wireless service in operation between the United Kingdom and Newfoundland, and several coastal stations have been erected.

Livermool and District Electrical Masters' Asso. the trade of Newfoundland and the Maritime Provinces of Canada,

Liverpool and District Electrical Masters' Association —A very successful informal evening of this Association was held at headquarters on Wednesday, 14th inst. As a good number of the members of the Association are with the Colours the attendance was not as heavy as usual, but the occasion gave the company an opportunity of expressing their appreciation of the patriotism of the members. The principal toast was "Absent Members at the War," and it was heartily received. Quite a feature of the evening was a stirring peech by Sergt. A. B. Gregson (Lanc. Fortress Royal Engineers), the chairman of the Association.

Zeppelin Raid and Lighting.—As a result of the airship raid on the N E. Coast last week, several cities were suddenly deprived of electric light for a time, and much inconvenience resulted. At Newcaetle both electric lighting and tramway services were suspended; at York the electric lighting supply was cut off for a time, and in Leeds and Hull similar precautions were taken, but the tramways were apparently not seriously interfered

#### ELECTRICAL CONCESSIONS GERMAN RUSSIA. IN

'As we have suggested already in discussing the future electrical position in Russia, a great deal may depend upon the attitude that the Russian Government assumes in regard to the German-owned electrical concessions and undertakings that have been operating for some years to the financial benefit of Germany from an investment point of view, and to the commercial and engineering advantage of that Empire by providing orders for electrical machinery and apparatus.

A number of years ago British commercial engineers and financiers spent no end of money and time upon negotiations to secure for this country concessions of first-rate importance in Russia, but for various reasons they were not In those days it was not for want of trying that we failed to secure both concessions and contracts for British firms. There can be little doubt that one of the most potent of the adverse influences that were at work was that exercised by German electro-financial concerns, and as the Russian Government pursues its inquiries into the position of particular undertakings, it becomes more and more obvious how effectively that influence was employed.

From what has lately appeared in our pages, it will have been observed that the Russian diplomatic world has been very much exercised respecting revelations that have been made, as the Government has, through the channels of a special Council, investigated the actual facts in regard to the character of the Petrograd Electric Lighting Co. of 1886, to which we referred last week. As we stated then, the Russian Government would hardly proceed with the liquidation of the company unless fully convinced of the almost entirely German nature of the undertaking. How much interest is being taken in the matter in Russia may be gathered from the fact that a copy of the Novoie Vremya recently received devotes four pages of one issue (Daily Telegraph size of page) to the matter. It seems that when the company was formed nearly thirty years ago it had a capital of only a million roubles, and it was established to carry out a concession granted to a German engineer by the then Minister of Finance. The company wanted its statutes based on German laws, but the said Minister desired it to operate according to Russian statutes. It seems not to have occurred to him that a German company operating with German money, through head offices in Berlin, was not a Russian concern, simply because for its Russian operations it rested on statutes more or less adapted to Russian law. As the concern prospered, its operations and capital rapidly grew until, in the spring of last year, the latter reached 40,000,000 roubles, and a fresh issue of 10,000,000 roubles was made in Berlin about that date, all of which reached the coffers of the Deutsche Bank, in accordance with orders given, two months before the war, by the Administration of the German Reichsbank, to detain foreign payments.

The concern acquired new markets in Russia, operating in Petrograd, Moscow, Pietrokoff and Lodz, while it also

extended its tentacles to embrace the utilisation of the famous Imatra Waterfalls of Finland. All of its endeavours appear to have been distinguished by that enterprise and confidence that came from its ability to count upon the powerful support of German diplomatic agents, and in this spirit, it appears from the Novoie Vremya, the managers of the company discarded the requirements of the Russian statutes and neglected the interests of Russian electricity users, with the result that there was frequent friction between the management of the company and the town authorities. The Moscow town councillors were particularly energetic, and in consequence relations became strained, and whenever it was sought by the Council to smooth matters over, these efforts were unsuccessful because the representatives of the Moscow branch were always able to say that they were without instructions from Berlin.

The situation eventually involved the intervention of the administrative powers, and in August, 1914, the Governor of Moscow appointed a special committee to examine the accounts and position of the said company and to maintain a watch over all its doings. This Committee submitted a comprehensive report to the Governor throwing light on the previously unobserved activity of German contractors in general, and of the 1886 company in particular. It was found that the Moscow administration and the Petrograd board were, right down to the war, in direct communication with the 1886 Electric Lighting Company in Berlin (Gesellschaft für Elektrische Beleuchtung vom Jahre 1886, Berlin), to which they applied for instructions

Berlin), to which they applied for instructions.

It was also decided that the Berlin company should control the construction of the new house of the Russian 1886 company, in Moscow, for which purpose a German architect was sent to superintend the construction of the house, and, subsequently, the Berlin control extended to such small matters as the engagement of employes of the company. Financially, the report shows that the Deutsche Bank of Berlin was at the head of the concern, and kept the funds of the company; further, when the question arose of the issue of fresh capital, a consortium of German banks was convoked in Berlin, at which all details of the issue were settled. The Committee supposes that all the 10,000,000 roubles resulting from the issue made in the spring of 1914 remained in the Deutsche Bank, in current account. A shortage of cash occurring, the Moscow branch applied at the beginning of July to the Petrograd house for money to pay its accounts; but it was informed that this could not be done, as the money that should have reached them out of the last operation was in the Deutsche Bank, Berlin, and that prudence should be observed in respect of expenditure.

As to the nationality of the shareholders there can be no doubt that most of the shares are in German hands, and only an insignificant number in Russian hands. Some of the nominally Russian shareholders are actually German, and, in actual fact, Russian shareholders own about 160,000 roubles value only—that is, about one-third per cent. of the total capital.

All the foregoing leads to the conclusion that the 1886 company is practically only in name a Russian company; both financially and administratively it is a German concern, and it is considered that the systematic evasion of any examination of the state of things in the Moscow branch, thanks to the special system of book-keeping, inspires no confidence that its further operations will not be prejudicial to Russia; and that therefore the 1886 company should be pronounced inimical to Russian Imperial interests and should be liquidated.

On the foregoing grounds the Government has been petitioned by the Town Council to arrest the activity of the company, but according to the Russian paper referred to, though the nature of the company has been fully exposed, and the members of the Government and the Town Council have unanimously agreed on the need for the earliest possible liquidation, there is no evidence of steps having been taken to carry the decision into effect.

British electrical firms are entertaining great hopes regarding the future of electrical engineering in Russia, and in view of that fact it is of interest to know as much as possible regarding the actual character of the past German operations there, which had given them so strong

a hold on the market, and also to observe the official attitude toward German-owned concerns, and to see whether, even now that the above report has been made, the liquidation recommendations will be actually carried into effect. It is hardly conceivable that the Russian powers in authority were in deep ignorance of the German character of the company, though they may not have known to what an extent the best interests of Russia were subordinated to those of the Germans concerned in the matter. No doubt the Russian authorities will see fit to assume control of the company, and include the matter when terms of settlement are under consideration at the end of the war. It may be that Belgian, French and British parties will then have a better opportunity than they have hitherto had in connection with the exploitation and conduct of electrical concerns in Russia.

Meanwhile, however, it is significant, as stated in our "War Items" to-day, that transfers of German-owned electrical undertakings in Russia are already being conducted in Belgium. It is reasonable to anticipate that such transactions will not be recognised by the Russian Government.

THE upward movement in the copper Copper. market seems to know no end, the rise sustained during the recent two or three weeks exceeding £10 a ton, while the indications seem to suggest the strong probability of a further advance in the near future. Far from showing any signs of a reaction, the tone remains as firm as ever, and producers in North America appear confident that the market will abate none of its firmness for a long time to come. It is abundantly clear that all estimates which were formed last Autumn as to the probable effect of the war upon the metal markets were based upon a serious misconception, and the tendency at the present time is to look for a further advance in values in all directions. Certainly production has fallen below the necessities of the buying which has been going on, and it must not be forgotten that a considerable proportion of the copper utilised in ammunition does not usually come back in the form of old material at a later date.

The prime consideration dominating the market at the present time is, of course, the large outlet which exists in connection with war requirements, and there should be a considerable increase before long in the production of refined copper available for this purpose. There seems to be no limit to the capacity of consumption, however, and there can be not the least doubt that the stocks of refined material awaiting disposal have been very much reduced during the last few months. It is only a few weeks ago that prominent American copper interests were booming the wisdom of the policy of small output and big price, but they seem to have been swept off their feet rather by the remarkable broadening in demands, and the tendency in all directions now involves a distinct increase in production. Very large quantities have been booked for export in the the United States within the last month or so, and the European demands show not the least signs of being reduced. Prices are reaching a very high level, and there has been a good deal of speculation initiated, but for all this the foundations of the market appear to be quite sound. The last few days have witnessed a good deal of new buying, both of refined copper and of warrants, and while the speculative element is not liked, the fact cannot be concealed that part of it comes from influential American quartersthe significance of which it would be foolish to disregard.

There has not been much passing in the general consuming trades, for all the plant available is running on Government work. American opinion inclines strongly in favour of record prices being attained, the opinion being based not only on the consumption for war purposes both in America and Europe, but also upon the fact that the home trade demands in the United States have lately begun to improve considerably, and there can be little doubt that if domestic consumption across the Atlantic reverted to anything like the average of the best months of last year, prices would receive a further sharp fillip.

4,

## THE ENGINEERING INDUSTRY AND ... THE WAR.

THE reassembling of Parliament has been followed by the inevitable opening of the floodgates of oratory. When the Houses were not in session we dared to hope that we should soon have some measure of relief from rumours that were so prevalent and persistent in certain circles. What the Censor, and the War Office behind that authority, did not see fit to divulge, might perchance escape the lips of some speaker in the Lords of Commons in some unguarded moment. The newspapers which are continuing to show irritation at having to suppress so much information that reaches them, are "agin the Government "whenever they are able to detect an opportunity for criticism, and they have found occasion to exercise their privilege in connection with statements made by different Ministers on the subject of the output of munitions of war. Now the majority of us have had quite enough of oratory for the present—we want to attend to the very important business that we and our Allies have on hand. And unless our Parliamentarians can show tolerable agreement in their policy and attitude toward things that are of vital moment, it were better that they should cross to Flanders and leave the "business" to men of "few words." Of critics and advisers all Governments that have attempted anything have had their share, and so many new problems have arisen during this European war period that the number could hardly be expected to decrease. The list of Special Committees that have been appointed from outside as the months have passed by, and the conferences that have taken place between members of the Government and authorities in financial and other walks of life, have shown the willingness of the Government to take advantage of the expert knowledge that has been lacking in its own immediate political circle. But we are bound to say that, if there have been too many critics, those who cast the blame therefor upon the Government—whoever that may mean—for keeping us in the dark, have our sympathy. It is not well in days such as these, when the issues involved are so enormous, that the people should have any want of confidence in those at the helm, and we profoundly trust that circumstances will speedily remove the grounds for grievance. that end let us have no more speaking than is really essential, providing opportunities for untimely quibbling or for efforts to make the statements of those who are working together to find ways and means for bringing this gigantic struggle to a successful issue, appear to be irreconcilable. We are reminded that Carlyle (in the "Latter Day Pamphlets") asked his readers to consider a body of 658 miscellaneous persons set to consult about "business" with 27 millions, mostly fools, assiduously listening to them and checking and criticising them. "Was there ever since the world began—will there ever be till the world end—any 'business' accomplished in these circumstances? The beginning of all business everywhere, as all practical persons testify, is decidedly this: That every man shut his mouth and do not open it again till his thinking and contriving faculty have elaborated something worth articulating . . . . This is the preliminary fundamental rule for business."

We were told a short time ago on very excellent authority that "shells—more shells!" were what we must have. Instead of every man who, by any stretch of the imagination, had anything whatsoever, direct or indirect, to do with the production of these, proceeding to increase his individual output, we found ourselves involved in discussions which certainly did not immediately assist matters. We revived all the old controversy about drink. Every manufacturer, we suppose, knew well enough, by

more or less lengthy experience, that drink was a handicap both to worker and to employer in normal times. But it was the fact that the workers had thousands of their own brothers sons fighting in the trenches, and if they had been allowed to know the truth there would probably have been strong influences at work among them-selves to reduce drinking. We have never thought selves to reduce drinking. We have never thought in normal times that the British workman would submit to his individual liberty being interfered with in this connection, any more than we have regarded him as willing to listen to reason concerning industrial quarrels, because his personal interests have always been paramount for him. But we have never lived in times like these before-may we never do so again!—and abnormal times call not only for exceptional measures from the nation, but for abnormal effort on the part of each individual having even a remote, part in fighting the most abominable foe of recent centuries. The reports regarding the effect of drinking upon output have varied very considerably. One deputation to Mr. Lloyd George showed that the weakness occasioned employers extreme concern. Other authorities say that they have had no adverse experience from drinking. Some say that better wages have enabled men to work only four days a week, and, self-satisfied, they have delayed the operations of others by absenting themselves the rest. Some of the works owners have complained that if men will insist on having their Saturday half-holiday (which we think they surely should dispense with now that they know the facts of the situation) their machinery lies idle when it might be operating. Some authorities have affirmed that long hours and continuous work wear men out if they have no Sunday rest, so that they become more susceptible to the drinking and Saint Monday habit. And so, by these and many other expressions of opinion, have we been brought into a state of chaotic thought regarding a social problem. and a big economic one, too, that has exercised ministries, Parliaments, social reformers, and, indeed, all of us more or less, for many decades. It will be a thousand pities if we spend our energies in time of war trying to find a quick solution for what the years have proved to be one of the most complex and involved of all our national problems. are confident in the assurance that powers are already in existence for dealing with the matter in time of emergency, and we believe that the firm hand of Lord Kitchener may be relied upon for dealing in an appropriate manner with the men who are traitors to their country and to their brothers on active service. We see difficulty in the way of a Government, which has given us the term: "not drunk in a police court sense," dealing with men who go back to work incompetent or inefficient because of fuzziness, but the Minister for War may exercise means that Cabinets view in other times with disfavour, yet which in time of emergency would have the moral support of practically the entire nation.

We are living in very heart-searching times, and we hope that this process of self-examination which the recruiting poster, the recruiting sergeant, the drum-beat of the highway, the message from the trenches, all induce, will bear fruit in the increased production of munitions as well as in the enlisting of fit men. The recruiting poster, the drum-beat of industry, and the call for "Shells! More Shells!!" might do much to influence the mind of the industrial worker, and lead, in conjunction with suitably restricted hours for public houses, to a greater moral force being brought into the factory fight, a fight within the man himself in order that he may do his best. "Be no longer a Chaos . . . Produce! Produce! Were it but the pitifullest infinitesimal fraction of a product, produce it, in God's name. 'Tis the utmost thou hast in thee: out with it, then. Up, up! Whatsoever thy hand findeth to do, do it with thy whole

might." Words of Carlyle these—in the "Everlasting Yea!" chapter of the Sartor Resartus. Written in another connection it is true, but how fitted to the present emergency—they would almost do for an Industry Recruiting Poster! They are, of course, not in keeping with the tenets of Trade Unionism as we have all known it. Limitation of output!—part of the gospel of Trade Unionism—how does that sound in these days of war? It has done its work—nobody can deny the character undermining effects of that damnable teaching. British workman at his best is a fine fellow, and he can beat his class in other industrial nations, but cannot have a work-limiting, suspicious, grudging policy or tendency controlling or influencing men for years without it leaving its after effects. Now is the time for the British workman to patriotically assist the land of his birth in her hour of trial by shaking himself as free as he can of those limitation shackles. Would that he would abandon them once and for all, and always do his utmost, then we should have little cause to fear the ruthless competition of the enemy in trade and manufacturing. At any rate, let us have freedom from these abominable self-imposed restrictive handcuffs when British blood is flowing out in Flanders. We are glad to learn from one of the daily papers that "an agreement has been come to between the Federation of Engineering Employers and the Amaling such trade union rules as tend to restrict output." Unquestionably trade union other part of our national life, is passing through its trial, and though it may seem premature to utter it, we will indulge a hope that it may, in respect of this output restriction question and some other matters, come through the fire refined, an altogether more creditable part of British national life, fostering the growth of a co-operation between employer and employé in manufacturing competitively and successfully for the good of all, so that Britain may have its full share of trade despite all comers.

The direction in which this output limitation has been leading has been witnessed at times in recent years in the intention which some workmen have expressed, without a trace of shamefacedness, to adopt a definite policy of doing as little as they can. An ingenious alternative to striking this—they would go in and take their money and simply do as little as they possibly could. To what depths of moral depravity we threaten to fall if this policy of common dishonesty be permitted—we cannot conceive of its being actually countenanced—by Trade Union organisations. We suppose that it would be considered impolitic to pursue this very distasteful subject at the present time, but it is useless shutting one's eyes to the facts, and, in our own opinion, if there has been shortcoming on the part of workers in producing manufactures, it has been in the case of a number of them the inevitable consequence of this output limitation policy, and its still more reprehensible offspring—the will to adopt deliberate slacking instead of striking. The strike habit, which for years past has been gaining a tighter hold upon industrial workers, has lately shown itself at its very worst. These men know what is right or wrong at a boxing match—would they not with one voice swear one unanimous oath if either were hit when he was down? Have they not shouted "Foul!" at football? Is there not honour even among thieves? Yet when their brothers are engaged in deadly struggle, when the land of their birth is fighting for its very existence—they are willing to assist the most rapacious and dishonourable foe that ever planted iron-heel in European soil? Cartoons are more forceful than oratory or written words, and they have played a fine part in recent events. They might be used to get the truth and very necessary arguments into the heads of all who are "producing" munitions to-day. In one very effective cartoon a British

khaki-clad hero, back from the front, is pictured in conversation with a discontented striking workman. "What would you have said of us in the trenches if we had struck for better pay?—but that's what you've been doing!" We are all of us having to carry sacrifices to-day—shall we justify Carlyle's description and strike? The British workman, when he complains of the cost of living, knows well enough that his services are so necessary that he can work overtime, and seven days a week, if he will, and get a bulging purse which will more than pay the increased cost and leave him something over for any bad days that may follow later.

We indeed hope, now that a little light has been poured upon the situation, and the pressing necessities are becoming better appreciated, that the men will everywhere trample down their own weaknesses—drink, strike, ca' canny and dishonesty—and "deliver the goods," carrying into immediate practice the "Aye!" which, at Mr. Asquith's meeting on Tyneside, thundered out their resolution to do their

best.

But not drink and labour disaffection alone are responsible for any apparent failure to "deliver the goods" as quickly as they were required. That it was not dreamt that ammunition would be used at such a rate as, for instance, at Neuve Chapelle, is a factor that it would be uncharitable to overlook. It is easy to criticise the powers in authority for what they have not done, and that we may leave to others or to a more appropriate occasion. Sufficient to say that actual requirements for the armies in the field have exceeded everybody's calculations. figures given by Mr. Lloyd George go to show that we have increased our rate of output at a greater rate than any of us had reason to suppose, but still the mobilisation of our industries is necessary in order that we may keep ourselves and our Allies supplied, and strong men and representative committees have been appointed to see that the thing is done. Not only have the industries to be mobilised, but the workers have to be found to keep every available piece of productive machinery employed.

When the call to the Colours was issued, from the ranks of the skilled engineering workers. and the miners, men left their places by hundreds of thousands-it was not foreseen that for what has proved to be an engineers' war, all our engineering labour would be required. It is stated that recruiting for the Army took 30,000 men from the Tyneside engineering district, and the question of bringing back from camp and from the Front some of these whose services are essential in the factories, has been under discussion; indeed, we believe that some have already been called back. Our own pages have borne evidence to the large drafts that have been made on the employes of engineering firms and companies in Manchester and other industrial districts, and we can only suppose that if it had been possible to foresee the engineering nature of this war, and the extent to which dependence would be placed upon us for the supplies of our Allies, many of these would have been dissuaded from going. Yet the recruiting sergeant is still active round our engineering shops! We are informed that Lord Kitchener sets no limit whatever upon our requirements, and it was stated in Parliament last week that that man was serving the cause most patriotically who was producing to the utmost of his Then why continue to draw them off power. from already hard-pressed factories where this producing is in progress? This mobilisation of works and workers has occasioned no little anxiety among the owners of small factories, who are fearful lest their men and machinery may be commandeered for service in bigger factories where it is more con-An appeal venient to manufacture what is needed. has been made to municipal authorities to release for factory service as many as possible of their

employés who are now engaged on things that, comparatively speaking, do not matter. When the great municipal strike at Leeds took place it was found that it was possible to dispense with certain classes of labour, and the appeal now made promises to lead to the release of thousands of men from other cities for productive operations in important manufacturing centres. These experiences may incidentally teach us some lessons regarding the more economical conduct of municipal affairs.

We believe that on the whole it has been shown that manufacturers are prepared to do their utmost to hasten the coming of victory by placing their resources at the disposal of the Government. We believe also that some of the difficulties due to want of organisation are rapidly disappearing, and if only the workers can be induced to "do their bit" with the same energy, zeal and self-sacrifice as characterise the conduct of our Forces in the Field, there will be little further cause for complaint. But it requires little special knowledge to observe that, in the present condition of affairs, many of our undertakings are too busily engaged upon Government needs to be able to make any important headway with efforts to "capture" our enemies' trade. 'capture' our enemies' trade. Commercial and selling staffs which have an undesired measure of relief from their accustomed vocations are doubtless not neglecting that matter but are looking well ahead.

#### THE FIGHT IN THE FACTORY.

#### BY "COMMERCIAL."

A NOTICEABLE feature of many of the recent annual meetings of manufacturing firms has been the oftrepeated statement that Government orders were on hand, such orders occupying the attention of a considerable part of the works' plant and labour. Usually these requisitions are in the general run of the products of the firm in question: in other cases -and these are not a few-men and machinery are being utilised to make certain articles or parts which are quite out of the beaten track. A motor-car works turns to special ordnance; an engine works to aeroplane parts; a locomotive works makes armoured trains; and so on. The man in the street may, or may not, be aware of all this business topsyturvydom. He may meet people who have laboured seven days a week for months on end, making ships, guns, shells, cables or cartridges. He may have seen the inspecting officers of H.M. Government sleeping on the test bed of some engine works, where engines are being tested for this or that battleship. cumulative effect of war upon work in the factory is, however, much greater and more complex than some people seem to imagine, and many new problems have arisen which are quite alien to the ordinary every-day perplexities of business. Of these, two are most important and most difficult of solution, the supply of labour and of material. Another which is, perhaps, only an aggravation of an old trouble rather than a new one, is the organisation of output

in accordance with customers' requirements.
